Communicable Disease and Pasteurized Milk

Pasteurized Milk Remains Safe Only With Proper Handling

By EDWARD S. GODFREY, JR., M.D., DIRECTOR, DIVISION OF COMMUNICABLE DISEASES, N. Y. STATE DEPARTMENT OF HEALTH, ALBANY, N. Y.

ADVOCATES of the pasteurization of public milk supplies have been aware that theoretically pasteurized milk may transmit infection unless the process and subsequent handling are under proper supervision. To what extent it has actually done so appears never to have been investigated. Originally proposed as a means of improving milk used for infant feeding, pasteurization was later adopted commercially for the purpose of improving the keeping qualities of market milk. This really amounted to sophistication when it was applied, as it usually was, to old or dirty milk. The practice was thereby brought into disrepute and its general application to municipal milk supplies was opposed not only by the laity but by many physicians and public health authorities.

This opposition still lingers with the laity and with a certain percentage of physicians, but health authorities are now almost unanimously in favor of pasteurization as the only practical means of avoiding milk-borne infections. They have been led to this conclusion by a realization of the high cost of keeping herds free from tuberculin reactors; a realization of the rôle of the carrier in the spread of acute infections—especially typhoid fever; the difficulties of early diagnosis both in typical and atypical cases of communicable diseases that may occur on dairy farms; and by the favorable experience of communities

which have adopted pasteurization. An improved rather than the relaxed dairy inspection that was expected, a legal definition of the term "pasteurization," and a closer supervision of the process by the constituted authorities, have combined to reduce opposition and to increase the public demand.

Safe in Safe Hands

Milk may be infected at the farm, the dairy, during delivery, or in the household. Pasteurization *per se* destroys only that infection introduced at the farm or in the process of handling at the dairy before being heated. If subsequently infected, transmission of infection to consumers is quite as certain as with raw milk. However, in most milk-borne outbreaks, the source of infection where this has been definitely ascertained, has been found at the producing farm. In 44 of the 64 instances of milk-borne typhoid cited by Swithinbank and Newman¹, sufficient details are given to determine quite positively the source of infection. In 75 per cent the source was at the farm, in 20 per cent at the dealers, and 5 per cent by drivers. The two instances of presumable infection by drivers or deliverymen are of interest in that the outbreaks were quite large as judged by the standards of today—30 and 31 cases, respectively—and one at least was explosive in character. Presumably the milk was "dipped" since one of the epidem-

ics occurred in 1877 and the other ten years later.²

A similar classification of the outbreaks cited by Trask³ shows that in 86 per cent the infection took place at the farm, while the Busey and Kober⁴ list shows 91 per cent. It should be understood that these percentages are based only on the outbreaks which are described with sufficient definiteness to assign the source either to farm infection or to subsequent infection. Of the 492 outbreaks described by these authors one hundred eighty-six could not be assigned to either group with any certainty.

A tabulation of the outbreaks cited by these authors is presented in Table 1.

As the outbreaks cited by the above mentioned authors occurred for the most part before modern dairy machinery came into common use, it is not surprising to find that our experience in New York state in recent years has been far different. Thirty-seven outbreaks in the state, exclusive of New York City, have been traced to milk since January 1, 1917. In

1. Swithinbank and Newman: Bacteriology of milk, pp. 316 et seq.

2. Parker: City milk supply, p. 324, states that the bottling of milk commercially began in New York City in 1878. Only two firms followed this practice prior to 1886, when a third company took it up. In 1896 only 10 per cent of the Philadelphia milk supply was delivered in bottles, and bottle delivery was not started in Chicago until 1895.

3. Trask, J. W.: Bull. Hyg. Lab. No. 56, pp. 51 et seq.

4. Trask, J. W.: Bull. Hyg. Lab. No. 56, pp. 118 et seq.

TABLE I.—SOURCES OF INFECTION IN MILK-BORNE OUTBREAKS.
(Trask, Busey & Kober)

Trask	ALL OUTBREAKS	Per Cent	Typhoid Fever	Scarlet Fever	Diph- theria
Total outbreaks	253	...	179	51	23
Indefinite	132	...	65	11	6
Definite	121	100	114	40	17
Farm infection	147	86	97	33	17
Subsequent infection	24	14	17	7	..
Busey & Kober					
Total outbreaks	239	...	138	73	28
Indefinite	104	...	40	45	19
Definite	135	100	98	28	9
Farm infection	123	91	92	23	8
Subsequent infection	12	9	6	5	1

thirty-five instances the source of infection was located on the farm itself and although the source was not discovered in the two other outbreaks, the chances were equally as good that it was on the farm as subsequently.

As will be shown later, not less than 22 per cent and probably about 30 per cent of the population of the United States in 1920 was supplied with milk officially recognized as pasteurized. While pasteurization under official supervision is of recent growth, yet for many years preceding the enactment of ordinances and rules defining and regulating the process, considerable amounts of milk were pasteurized for commercial purposes. It would be expected that with this large amount of pasteurized milk being sold, some subject to official oversight and some not, that outbreaks of communicable disease transmitted by such supplies have occurred.

In order to ascertain how often these have happened, and in order to discover if possible the faults that have been responsible, an effort has been made to collect all outbreaks of communicable diseases attributable to pasteurized milk. An inquiry was addressed to the executive officer of every state health department, to the health officers of twelve of the largest cities in the United States, and to several of the most prominent teachers in public health schools. This inquiry was intended to cover all outbreaks of communicable diseases in which milk that was pasteurized, or even purported to be pasteurized, was found to be or was suspected of being the agent of transmission. The questionnaire covered not only outbreaks occurring in the experience of the person to whom the inquiry was sent, but any that might have occurred in his state or municipality or which he recalled having encountered in the literature. As a result sixteen outbreaks have been collected, the summaries of which are given in Table II.

It is not pretended that this list is complete for the inquiry was confined to those most apt to know of instances of this sort either through personal experience, through their official po-

sition, or through their known interest in the improvement of milk supplies. All such outbreaks must have occurred in recent years and therefore within the recollection of men probably still active in public health work. It is hoped that any omissions from the list will be supplied and that future outbreaks will be reported as such, since it is important that we do not allow the term "pasteurization" to become a shibboleth. I believe that too many health officers are prone to assume that because milk passes through a pasteurization plant it is *ipso facto* safe. Many of the replies received to our questionnaire stated that an outbreak due to pasteurized milk was impossible, showing that they either misunderstood the questions or that they failed to appreciate the necessity of careful supervision.

To summarize these outbreaks, it will be noted that three—Outbreaks Nos. 1, 2 and 3—were due to milk pasteurized by the so-called "flash" or continuous process, only one of which (No. 2) was subjected to official supervision. This was the Chicago septic sore throat outbreak of 1911. The Chicago ordinance of 1908 gave, I believe, the first legal definition of pasteurization. It permitted any method which resulted in a destruction of 99 per cent of the total bacteria and all the pathogenic bacteria contained in the raw milk. The pasteurizer in this case was equipped with a recording thermometer and, as shown in Capps and Miller's article, there was a marked correlation in the time between the failures of the temperature to reach the necessary thermal death point for this machine and more outbreaks (Nos. 1 and 3) there was apparently no attempt to meet the peaks of the onsets of the cases.

In the Little Rock and Balti-

any legal requirements. The former was an extensive typhoid outbreak of about three hundred and thirty cases, the summarized account of which has been furnished by Dr. W. H. Frost,⁶ Johns Hopkins University, Baltimore, Md. The milk was sold partly in bottles, partly in bulk to an institution, and partly as ice cream. There was no thermographic record of the pasteurizer and, although the source was not definitely located, the milk

TABLE II.—A SUMMARIZED STATEMENT OF SIXTEEN OUTBREAKS OF COMMUNICABLE DISEASES ATTRIBUTABLE TO PASTEURIZED MILK*.

- (1) Little Rock, Ark., 1911. Flash pasteurization. Typhoid, approximately 330 cases. Source of infection not determined.
- (2) Chicago, Ill., 1911-1912. Flash pasteurization. Septic sore throat, approximately two thousand cases. Source of infection: probably cases on dairy farm. Also, one case among workers at pasteurizing plant.
- (3) Baltimore, Md., 1912. Flash pasteurization. Septic sore throat, between four and five thousand cases. Source of infection unknown; probably infection was introduced before pasteurization.
- (4) Rockford, Ill., 1913. Holding pasteurization. Typhoid, from 16 to 31 cases. Source of infection: exchange of bottles with another dairy; evidence as presented not conclusive.
- (5) New York City-Brooklyn, 1915. Holding pasteurization. Typhoid, 112 cases. Source of infection, mechanical bottle filler infected by polluted water used in washing.
- (6) New York City-Bronx, 1916. Typhoid fever, 55 cases. Source of infection: Country pasteurizing plant in village where typhoid record was "bad," 19 cases being recorded in six or seven years in population of 250.
- (7) Charlottesville, Va., July, 1916. Holding in bottle pasteurization. Diphtheria, 12 primary and 3 secondary cases. Sources of infection: bottles capped by hand; wife of capper gave positive throat cultures; capper negative; adults, one child only.
- (8) New York City-State Island, 1917. Holding pasteurization. Typhoid fever, 65 cases. Source of infection not definitely located; a driver was found who had two cases in family.
- (9) Somerville and Medford, Mass., 1917. Holding pasteurization. Septic sore throat, approximately 150 cases. Source of infection: thermograph out of order for a time prior to outbreak; three employees of plant complained of sore throat.
- (10) Hartford, Conn., 1920. Holding pasteurization. Typhoid, four cases. Source of infection: all cases on route of one driver who was found to be a typhoid carrier.
- (11) Providence, R. I., 1920. Holding pasteurization. Scarlet fever, 29 cases. Source of infection: all cases occurred among students eating in a certain refectory; no cases among other customers of same dairy; Chapin believes possibly can of raw milk was substituted.
- (12) Canby, Minn., 1921. Pasteurized by being brought to temperature of 160 degrees in "starter can" and immediately cooled. Typhoid fever, six cases. Source of infection: unrecognized case in family of proprietor of milk plant; equipment and process did not conform to state requirements, and products not sold as pasteurized.
- (13) Minneapolis, Minn., 1921. Holding pasteurization. Paratyphoid, approximately one hundred cases. Milk was properly pasteurized; sold in bulk to cafeteria at University.
- (14) Pennsylvania, August to October, 1916. Holding pasteurization. Typhoid, approximately fifteen hundred cases. Ice cream outbreak centering in Harrisburg; source of infection not discovered.
- (15) Chattanooga, Tenn., July and August, 1917. Flash pasteurization. Typhoid, approximately seventy-five cases. Source of infection not determined.
- (16) Hartford, Conn., 1921. Holding pasteurization. Typhoid and paratyphoid, 83 cases. Source of infection not determined; outbreaks or unusual prevalence of typhoid or paratyphoid in communities in which this ice cream was sold.

Note—Reference in discussion is by paragraph number.

was probably infected before pasteurization. The Baltimore outbreak was the well known outbreak of septic sore throat. Since this has been adequately described in the literature, it suffices to say that infection almost certainly took place before the milk reached the pasteurizing plant and that no adequate thermographic records were available for the period during which infection took place.

One other outbreak which possibly belongs in this category was that in Canby, Minn. (No. 12). This was a typhoid fever outbreak of six cases.⁷ The source of infection was thought to have been a child suspected of having had unrecognized typhoid in the family of one of the proprietors. While the "flash" method of pasteurization, as that is ordinarily understood, was not used, neither did the process conform to the state requirements. The milk was run into a fifty gallon "starter can" and the temperature then raised to from 160 to 180 degrees F. A common dairy thermometer was used for determining the temperature. After attaining the temperature stated above the milk was immediately cooled, transferred to cans, and stored in a refrigerator. It was dipped from these cans into containers furnished by the consumers as it was called for at the plant. The milk was not advertised or labeled as "pasteurized," the sole object of the process being to improve the keeping qualities of the milk.

Fault One of Method

The "flash" method soon fell into such disrepute among health officials that milk subjected to this process is no longer officially recognized as pasteurized. It is very probable that there have been other outbreaks due to this type of "pasteurized" milk which either have not been reported, or if reported, this sort of "pasteurization" was considered immaterial and unworthy of mention. It should be borne in mind too, that formerly milk-borne typhoid was very apt to be masked by the large numbers of water-borne cases, and that the widespread use of good epidemiological methods is a matter of the last decade at most and is not yet universal. Hence it is not unlikely that a number of small milk borne outbreaks have been overlooked and among these there may have been some on pasteurized milk routes.

Of the remaining twelve outbreaks, there was one each of scarlet fever,

septic sore throat and diphtheria, and nine of typhoid fever. The scarlet fever outbreak—No. 11—occurred in a refectory at Brown University and Doctor Chapin⁸ after a careful investigation was unable to discover any way by which the milk could have become infected after pasteurization, and the fact that no cases occurred among customers of this company outside the refectory precluded faulty pasteurization. His conclusion was that someone had surreptitiously introduced a can of raw milk which had chanced to be infected.

The septic sore throat outbreak in Massachusetts (No. 9) may have been due to defective pasteurization or to infection introduced subsequently.⁹ The thermographic records of the pasteurizer for several days preceding the outbreak "could not be found," and on the other hand three of the employees in the plant were suffering from sore throat while at work.

The diphtheria outbreak in Charlottesville, Va., (No. 7) is interesting as it illustrates the danger of human handling subsequent to pasteurization. I am indebted to Dr. Enion G. Williams, secretary of the Virginia State Board of Health, for mentioning this outbreak and for obtaining the manuscript of the paper by Dr. W. E. Bray describing it. This milk was pasteurized in the bottle by the holding process but was capped by hand. The capper was observed to wet his finger on his tongue from time to time in order to facilitate his work. Although a day or two after the outbreak commenced his throat cultures were negative, his wife's cultures were positive. It is not difficult to believe, in the absence of evidence as to other possible avenues of infection, that he had been a transient carrier and had infected the milk by his fingers or by coughing into the open bottles.

Reverse Age Incidence

This outbreak is also of interest in that only one child was attacked. Although the outbreak was mostly among students of the University of Virginia, a number of children drank the milk without contracting the disease. This is another illustration of the peculiar tendency of milk outbreaks to reverse the usual age inci-

dence of the disease. This peculiarity has not been specially mentioned by American authors except for typhoid fever. We have had three illustrations of it as to diphtheria and scarlet fever in New York state this year. Ordinarily about from 15 to 20 per cent of our diphtheria and scarlet fever cases occur among persons over nineteen years of age. In one of these milk-borne scarlet fever outbreaks the percentage of cases over twenty years was twenty-eight, in the other thirty-two, while in the diphtheria outbreak it was sixty-nine, with no peculiarity of age distribution among the exposures to account for it. We ordinarily consider the adult relatively immune to these diseases, presumably either because of a prior attack or from repeated exposure to small amounts of infection, and yet they readily succumb to infection transmitted by milk. This susceptibility of adults to scarlet fever and diphtheria is the more remarkable when we consider that in milk-borne typhoid we ordinarily find a disproportionate number of cases among children and this is usually ascribed to their consuming more milk. If the latter be the true explanation in typhoid, it is peculiar, to say the least, that it does not hold true, in scarlet fever and diphtheria.¹⁰

Of the nine typhoid outbreaks, one occurred in Rockford, Ill., one in Hartford, Conn.; one in the University of Minnesota—a paratyphoid outbreak, to be exact; three were in New York City; and three were ice cream outbreaks occurring in Pennsylvania, Chattanooga, Tenn., and Hartford, Conn.

The Rockford, Illinois, outbreak—No. 4—formed part of a general outbreak of 165 cases which occurred in that city from July to October, inclusive, in 1913.¹¹ The plant was a "thoroughly equipped, modern, city milk plant, and does, by far, the largest milk business in Rockford." The milk was pasteurized by the holding process and apparatus was provided for sterilizing the cans and bottles. No evidence is adduced that the pasteurization was not properly carried out or that cans and bottles were not properly sterilized, yet the authors surmise that infection occurred through the use of bottles from another dairy which was having a number of cases on its route. As a

matter of fact, the evidence that this particular milk conveyed infection is, as presented, far from conclusive. Suspicion was aroused because the number of cases on this route increased from three in August to nine in September and fifteen in October. However, this plant supplied 43 per cent of the total milk of the city and in no month did it have more than 36 per cent of the total cases in the city for that month. The increase in the number of October cases can probably be accounted for by an increased business at that time in that part of the city which was principally affected by typhoid. A milk plant located in this affected section had been shut down on September 4 and it is a fair assumption that the suspected plant got a share of its business."

The Hartford outbreak (No. 10) consisted of but four cases, all on the route of one milk driver found to be a carrier¹². This is an example of careful epidemiological work and it is to the credit of the health department that an outbreak of this size should be recognized promptly and traced to its source. An outbreak of this character is in conformity with what might be expected from the handling of milk bottles in the course of delivery by a case or carrier.

New York City Outbreaks

In the account¹³ of one of the New York City outbreaks (No. 8) it is mentioned that a driver was found in whose family two cases of typhoid existed. Apparently considerable significance was attached to this, since the account related that the outbreak ceased soon after he discontinued work. As this outbreak was explosive in character and involved sixty-five cases, the suggestion of cause and effect is difficult to believe. The epidemiological account does not state as a conclusion that the driver was the cause of the outbreak, but the uncritical reader is very apt to receive this impression. As a matter of fact, how the milk became infected in this case was never determined. That it was subsequent to pasteurization seems amply proved by the fact that the process and method of handling at the plant were satisfactory, and milk from this plant going elsewhere in New York transmitted no typhoid.

Another of the New York City out-

breaks (No. 5) was attributed to the water used in washing out the bottling machine after it had been sterilized by steam¹⁴. The milk was pasteurized in a plant from which it was delivered to several dealers who did their own bottling. The milk of one bottling plant only had an excessive typhoid incidence. No cases or carriers could be discovered among the personnel, but upon analysis the water supply showed pollution.

The remaining New York City outbreak (No. 6) was attributed to infection occurring in the country village where the milk was pasteurized and whence it was shipped to New York¹⁵. Just what defect permitted infection to survive pasteurization or gain entrance subsequently does not appear to have been determined. The report states that the typhoid record of the village was "bad," implying presumably that there was an unknown carrier employed in the plant who might have infected the milk after pasteurization.

Faulty Pasteurization

The paratyphoid outbreak at the University of Minnesota (No. 13) was quite certainly due to infection subsequent to pasteurization¹, although the precise mode of infection if known has not been stated. The milk was delivered in bulk to one of the cafeterias at the University and presumably was infected by some employee.

The three ice cream outbreaks occurred in Pennsylvania, Chattanooga, Tenn., and Connecticut. The Pennsylvania ice cream outbreak (No. 14) is of interest as being the most extensive milk-borne outbreak of typhoid fever on record, the term "milk" being used to include "milk products." This outbreak, involving nearly fifteen hundred cases, extended to twenty-one counties in Pennsylvania and should probably include a number of cases in other states to which the product from the infecting factory was shipped¹⁶. It seems remarkable that so recently as six years ago an outbreak of typhoid could reach such magnitude and either have remained so long unrecognized for what it was or have been dealt with in such an uncertain manner.

The method of pasteurization was to raise the temperature of the cream to 160 degrees Fahrenheit, after

which it was cooled to 140 degrees and there held for twenty to thirty minutes. It was subsequently cooled to 45 degrees in an open vat and afterwards passed to a homogenizer. There were no recording thermometers and it is related that one thermometer was not in good working order so that it was doubted if the cream reached or was held at the temperature claimed. Examinations of the efficiency of the pasteurizer taken three to ten weeks after the plant was under suspicion, showed that colon bacilli were passing through in large numbers. The pasteurization of this cream was not subject to official supervision prior to the outbreak. The source of infection was never determined.

Dangers in Ice Cream

This outbreak is of especial interest since it illustrates the potential magnitude of an ice cream outbreak. The consumption of ice cream has grown enormously and the supervision of its production has not kept pace with this growth. While most large factories pasteurize their cream for business reasons, this pasteurization often is not subject to the requirements pertaining to the pasteurization of market milk. The modern ice cream plant turns out thousands of gallons of its product every week during the season when typhoid infection is most apt to occur and it is not unreasonable to require that not only should the process of pasteurization be subject to supervision, but that every step in its manufacture should be under official oversight.

The Chattanooga outbreak (No. 15) comprised about seventy-five cases. "The mixture for making the ice cream . . . was run through a 'flash' pasteurizing machine, but it was positively established that this machine on some occasions did not pasteurize¹⁷." The source of infection was not located.

The Connecticut outbreak (No. 16) was apparently due to a double infection since it consisted of 45 typhoid and 32 paratyphoid cases in Connecticut and 6 typhoid cases in a small hamlet in New York¹⁸. The ice cream was distributed to forty communities outside of Hartford, in eleven of which one or more typhoid cases occurred about the same time as the main outbreak in Hartford. The milk and cream used were condensed, homogenized, or pasteurized. The temperatures at which the processes of

condensation and homogenizing were carried on are not stated but all milk and cream is said to have been pasteurized before reaching the jobbers who supplied the ice cream company. The temperature records of the pasteurizing plant whence came the uncondensed cream were available and showed that pasteurization had been properly performed. In the process of manufacture the cream (condensed, homogenized, or pasteurized) was raised to a temperature of 150 degrees Fahrenheit in a large vat. The addition of sugar was commenced at this point and completed in from twenty to twenty-five minutes, at which time the temperature was ordinarily about 125 degrees F. Other materials were then added and the product piped to the freezers. All likely sources of infection appear to have been investigated with negative results. It is hardly profitable to speculate on the sources of infection since but few of the possibilities can be definitely excluded on the evidence it was possible to secure. It is believed, however, that the pasteurized cream can be definitely excluded since the firm which supplied this cream also sold milk at retail and the cases which developed on its routes also ate the ice cream. Both this outbreak and the one in Chattanooga were explosive in character, a high percentage of the cases developing within a single seven day period in each instance.

Pasteurization Increases

It has already been mentioned that probably about 30 per cent of the population of the United States was supplied with pasteurized milk in 1920. This figure was derived from the report of the Committee on Municipal Health Department Practice and Milk Inspector Letter No. 57, United States Department of Agriculture. In the former report¹⁸ is given the percentage of pasteurized milk sold in each of seventy cities of over 100,000 population. The weighted average of these figures shows that 83 per cent of their total milk supply was pasteurized. The combined population of the cities of 100,000 was in 1920, 27,429,326, or 26 per cent of the total population of the continental United States. Therefore, approximately 22 per cent of our population was quite certainly served with pasteurized milk that year. A conservative calculation based on the milk inspector letter above referred to adds approximately

seven million living in cities of ten thousand to one hundred thousand population, whose milk supply is pasteurized. This is 6.6 per cent of the population of the United States, making a total of 28.6 per cent of the population who consume pasteurized milk. To this a small number should be added for those living in smaller communities, principally suburban, who obtain pasteurized milk, bringing the total to about 30 per cent.

While the increase in pasteurization has been rapid, yet it has not developed all at once and it is apparent therefore that this small number of outbreaks on pasteurized milk routes is not merely a matter of chance. Although we have no way of knowing how many milk-borne outbreaks have occurred during the period of eleven years covered by the series here reported, it has quite certainly run into the hundreds. If quantity alone were the determining factor we should probably have from ten to twenty times this number of outbreaks to report.

Perhaps the most convincing evidence of the benefits of pasteurization from the standpoint here considered, is to be found in the contrast between the experience of New York City and New York state, exclusive of the city, since January 1, 1917. Although in 1921 about 54 per cent of the milk supplied "up-state" by licensed dealers was pasteurized, it is probable that when milk consumed by owners of cows and that sold to neighbors is included, that the percentage of pasteurized milk would not exceed 35 per cent. In New York City 98 per cent of the milk is pasteurized. The population of New York City is 15 per cent larger than that of the rest of the state and much of its milk is shipped from considerable distances. During this period the city has had one outbreak—a typhoid outbreak five years ago (No. 8) while thirty-seven have occurred in the rest of the state. This is certainly a remarkable contrast even making allowance for the fact that outbreaks and their sources are more easily discovered and traced in smaller places than they are in large ones.

Apocryphal of the tracing of outbreaks, there is a word to say relative to the epidemiology of milk borne typhoid. There is a prevalent belief, handed down from the last generation, that all milk borne typhoid appears explosively. This was formerly thought to be true of water-borne typhoid. But just as improved methods of treating water from polluted sources have reduced the in-

cidence of water-borne typhoid, and yet by reason of minor or temporary defects have allowed occasional infection to occur, so will it probably be with milk borne typhoid as the extent of pasteurization increases. There will be a considerable reduction in the gross amount of typhoid fever—greater than the figures for definite milk-borne outbreaks seem to indicate¹⁹, but there will be residual cases whose source will only be located by careful epidemiological study.

Occasionally the pasteurizer will kill almost but not quite all of the pathogens in a primarily infected milk, or possibly it may attenuate their virulence though not killing them, or a bottle will occasionally be infected by a carrier in the plant or on the wagon, and the result will be a few scattered cases of typhoid occurring perhaps weeks or months apart. This kind of milk-borne typhoid is rarely discovered today but it is the kind that we must learn to discover if milk-borne typhoid is to be no more.

Summary and Conclusion

Sixteen instances have been collected of outbreaks of communicable disease attributed to infection by milk, or milk products, which had been—or purported to have been—pasteurized. In one instance the milk probably had nothing to do with transmitting infection. In four instances the milk was pasteurized by the "flash" system or some other method which failed to conform to the standards of the health authorities. In one instance, the thermographic records for several days preceding the outbreak could not be found, hence there is a doubt as to whether a proper temperature was reached and maintained for the proper length of time. In this instance there was also an opportunity for the milk to have become infected subsequent to pasteurization.

In seven instances in which pasteurization was properly carried out, the evidence as to subsequent infection is conclusive in all but two. This is demonstrated by the fact that milk from the same pasteurizing plant handled by other dealers or drivers or delivered elsewhere than in the sharply defined focus of the outbreak did not spread infection. In one of the two exceptions there was very strong

circumstantial evidence of infection by the employee who capped the bottles. In the other the source of infection was not located. Although it could be considered that infection *may* have passed through the pasteurizer, there is no evidence that it did.

Hence it is a fair conclusion that pasteurization as now commonly defined in health laws and regulations will destroy any infection implanted previous to the process. Since from 85 to 90 per cent of milk outbreaks have been due to infection at the farm, pasteurization will prevent from 85 to 90 per cent of milk-borne

infection. With modern dairy machinery which reduces human handling to a minimum and provides ample facilities for the sterilization of utensils, the number of infections occurring through milk will be infinitesimal. The remaining sources of danger are slight except in hotels, restaurants, boarding houses, and in shops where bulk milk is permitted to be dipped. The fact that it has been possible to collect these reports of outbreaks emphasizes the necessity of supervising the process of pasteurization and of properly protecting the product afterwards.

The potential danger from infected ice cream is illustrated by three outbreaks, especially the enormous typhoid outbreak cited. The manufacture and handling of this widely consumed product is deserving of closer supervision than that of any other food product except milk itself.

Milk-borne typhoid will probably tend to assume more and more an endemic type as pasteurization becomes more common. It will therefore demand more intensive investigation in order to determine the mode of transmission and locate the case or carrier responsible for the infection.

Eugenic and Dysgenic Classes

By H. H. NEWMAN, PH.D., PROFESSOR OF ZOOLOGY, UNIVERSITY OF CHICAGO, CHICAGO, ILL.

ONCE upon a time there was a typical kingdom, ruled over by a decidedly atypical king. This king, instead of looking upon his people as a property intended for purposes of exploitation, had the highest and best interests of the whole people at heart. Looking over his people he saw that some were plus quantities and other minus quantities, in so far as their individual values to the community at large was concerned. Having arrived at this conclusion, he decided that, since he was all powerful and could accomplish whatever he chose, he would do a little problem in human arithmetic by way of increasing the total value of the human elements in his kingdom. The thing to do was very simple—subtract the minus quantities and multiply the plus quantities. In a generation the results were amazing. No more feeble-minded, insane, weakling, or criminal folk were born within the kingdom. All of the babies were the offspring of selected parents with plus values. Human evolution had jumped forward by leaps and bounds. All were happy and contented. The few inferior types that were still surviving were kept in isolation or else were sterilized so that they were the last of their kind—mere human curiosities, relics of a primitive, barbarous age.

So goes my little fairy tale. What is wrong with it, may I ask you? Suppose in the United States today some very highly trained and very wise and judicious eugenicist was given full power to carry out a eugenic program. Would he be able to repeat the success of our fairy tale king? Let us examine his task before we attempt to decide.

First, he must be able to distinguish

between the plus quantities and the minus quantities. That in itself would be a difficult task. One would have to study pedigrees before one could pronounce upon the value of an individual. Granting that this could all be done if the eugenicist had adequate assistance, would he then be able to carry out his plans? He might, if he were a truly far-sighted individual and one able to see with a wide-ranging social perspective. He must judge between the plus and minus quantities with reference to their service as members of a highly complex social organization. Who are the eugenic classes, the plus types we have been speaking of? Who are the dysgenic classes, the minus types of our story?

I am sorry to say that almost everything that has been written about the so-called superior classes, about subsidizing the fit, about conserving the desirable germ-plasm, has for its basic assumption that the eugenic classes are the intellectual classes. It has been pointed out that the leading American men of science have far fewer children than they should, that graduates of the leading womens' colleges have on the average about half a child apiece, that the old New England stocks, which are, of course, admittedly superior, are gradually dying out, especially in their native haunts.

In a word, it would appear that the writers on eugenics have simply assumed that their own types are the eugenic types and are sad because these types are losing ground. They would advocate various measures for giving these stocks an artificial advantage in the struggle for existence, so that considerably larger numbers of such types might be produced than

could find a foothold under present conditions.

This effort is, we believe, ill conceived. We are a great agricultural and industrial community and we need a number of distinct types of humanity in pretty definite ratios in order to run smoothly. We need many agricultural types, many industrial or artisan types, many commercial or purely business types, a relatively few executive types, and some intellectual types. We have arrived at a working equilibrium with reference to the ratios of the types that the great business of the nation needs. My critics will answer that there is no such classification of human types as those that I have listed. My reply would be that, roughly speaking, I am right. Who knows better than the university professor how almost impossible it would be for him with his mental endowment to perform day after day the tasks of a shoe-cutter, tasks that require some manual skill but no intellectual activity. Such an occupation would much better be performed by a man of simple, uncomplex mentality, one who will not suffer agonies for the lack of mental excitement. The skilled mechanics and those who are manually the most effective are not the intellectual types, nor are they commonly the executive types. I maintain that there are several distinct categories of eugenic types and that they reproduce themselves just about as rapidly as is necessary to maintain a nice equilibrium of the various types in the complex community. The task of unbalancing this equilibrium would be a difficult and probably an undesirable one. It will be seen that I am somewhat pessimistic with regard to so-called positive

eugenics We would best let well enough alone on the side of the plus elements in our country, but there is ample room for action with reference to the minus quantities.

Obvious Things to Do

There is some positive knowledge as to what constitute the dysgenic classes. The patent feeble-minded, the types tainted with known forms

of hereditary insanity, the types belonging to pedigrees whose sum total of achievement falls on the debit side of the balance sheet; these types are obviously minus quantities in our communities. They contribute nothing of value to the sum total of human welfare. The cutting off of these stocks, of these streams of germ-plasm, would be comparatively easy. A vast improvement in condi-

tions of life would be felt in a generation. At present it need not be a matter of great concern for us to attempt to alter the equilibrium of the plus classes. It is too soon to try an experiment so difficult and fraught with so much economic danger. But the experiment of eliminating the obviously unfit, the patently dysgenic classes, is one that should be begun at once and on a large scale.

Elements of a Health Education Campaign

Formation of a National Health Education Commission Recommended

By R. E. LUHN, JR., EXECUTIVE SECRETARY, TUBERCULOSIS SOCIETY OF OKLAHOMA CITY, OKLAHOMA CITY, OKLA.

INASMUCH as a health education campaign successfully to enlighten all branches of society, comprising probably 90 per cent of the total, now ignorant to a remarkable degree of the diverse elements affecting bodily health, must react on high and low, rich and poor, young and old, it should not be a sporadic and haphazard undertaking but should cover the nation and be continuous. To conduct such a campaign in a way to insure the largest measure of success nationally would probably require a committee or commission to include experts on preventive medicine, public health, psychology, education, and practical applied advertising.

There is reason to believe that many of the health education campaigns now conducted by local tuberculosis societies, Red Cross chapters, and health departments are a waste of time, effort, and money. A common method is to placard the town with "don't-spit" or other posters which are to "educate" the public. All available car-card and bill-board space is used. Two minute speakers fill the theaters. Dodgers litter the streets. The public for a week or ten days is literally stuffed with health education, so called, with little of it digested. Two days after a campaign of this nature nothing much remains of it.

Fortunately, all organizations do not depend on this intensive "get it over quick" method. There is a steady, sane health education campaign being conducted along right lines in numbers of places, particularly in the larger cities, by public health nurses, public spirited physicians, and social workers, but this, even, is not broad enough, reaching only a small percentage of our urban population

and the rural population scarcely at all. There is little coordination of program in the different centers and but a fraction of the effort which should be exerted annually to enlighten the people concerning health matters is brought into play.

In any undertaking the object of which is to educate the adult population care must be taken not to underestimate the ability of our American public to grasp even technical information if presented in clear, understandable language, else the very object aimed at will be lost. Undoubtedly, one of the most effective ways to reach the American people is through the use of paid space in newspapers and periodicals. Dignified, attractive advertisements are read, and when

read are absorbed. Preparation of such advertisements, so far away as type display is concerned, should be in the hands of an advertising expert. The presentation to the eye should be as nearly perfect as human ingenuity may devise. The language should be strong, simple, effective. The information offered should be in itself comprehensive, but possibly through the use of a coupon, an offer should be made in each advertisement to furnish pamphlets giving more detailed information on the particular subject treated.

The newspapers of the day are besieged from all sides by health educators and others for space, a community with a definite sale value. The greater part of the material of-

ferred is not "news," however valuable in itself as educational material. No health society that has the money will hesitate to spend a given sum for leaflets, pamphlets, booklets galore. Why the hesitancy to lay out money in a way that would get certain, fixed results, paying for display space, asking only of publishers contributions for the support of the work on the same basis with others? This policy should result in health becoming more and more a news subject in a true sense, finally carrying such weight that paid space would be required to a less degree.

Facts presented to the public through paid space would require careful reviewing. Public health work is greatly hampered today because information disseminated in the past was either false to begin with or later disproved. It probably would be impossible and possibly not desirable to prevent local organizations from indulging in health education campaigns of their own, especially along publicity lines, but with a national committee to pass on the methods employed and the information disseminated, this desire for individual expression should become a source of strength to the movement.

Is the idea of creating a public health education commission a practical one, particularly from a financial standpoint? If all the money now expended in hodge-podge health education methods over the entire country could be concentrated we would undoubtedly have sufficient funds with which to finance such a commission: or the work might be undertaken under the existing National Health Council.

Health education involves the changing of habits, not of individuals but of the nation. Take for example the practice of promiscuous spitting which has been recognized as a habit exceedingly dangerous to health and disgusting in nature. It is an unnecessary habit, as unnecessary as defecation in public, or other practices injurious to health, morals, or ethics which have been discarded in the rise of the race from savagery. Recognizing these facts, it is natural for our health organizations to make strong efforts to do away with the spitting evil, but the net results of the combination of education and legislation towards checking the practice, has been up to now, almost nil. Undoubtedly, in the course of a hundred years or more present day methods for curbing the practice would have the desired effect, but if an immediate change is wanted we must not merely convert

a few people in this town and a few in that. We must convert fifty to seventy-five per cent of the population. We must finally have the whole population in that frame of mind in which the man who spits or coughs or sneezes improperly is considered without the pale, and so with other false practices. A national committee amply financed should be able to accomplish this result very quickly.

Instilling in the minds of the adult population certain basic health truths would be only part of the work of a national health education committee, and the use of advertising space is only one of the methods that might be employed in carrying out its program. Pamphlets and bulletins are used largely now to give detailed information on health matters to the public. The tendency is to furnish the public with scientific information, —to let them in on the "know." The idea is of course the correct one but the vehicles now used for putting it into operation are almost invariably bad. Board of health bulletins and pamphlets are subject to much criticism for their general unattractive, dry-as-dust methods of presentation. A national committee could do much towards standardizing such publications to a form that would be acceptable to the public.

Probably the most important undertaking remaining undone in the realm of health education today is the formulation of a standard course of study on health for our public schools, colleges and universities. The movement or system known as the mod-

ern health crusade is the only nationally used method of health instruction in vogue in our schools today. The crusade teaches eleven elementary health rules. It is best adapted to small children, though it is being developed for extension to older boys and girls. Objections to the crusade have been raised by educators, among the most important of which are: that even in instances where it is included as a part of the curriculum it is in reality an outside movement; another, that it is difficult to continue the crusade in the same school year after year. What is needed in our schools is a graded course, based on the crusade for the lower grades, but departing from such elementary methods with the advance in grade. The crusade is not so much a method of teaching hygiene as it is of teaching health habit formation. This is indeed an important thing to do and the principles involved should be kept before the children and enlarged on through all the grades.

In the teaching of physiology and hygiene stress heretofore has been laid on nomenclature of organ, bones, and muscles, rather than on function. History once was taught much in the same fashion. Now the process with history is entirely changed. Dates and names are so interlinked with events past and future, that the interest and attention of the pupils are aroused, with consequent retention. Thus was an educational problem successfully solved by applied psychological methods, which may as easily be adapted to health teaching.

With the advance of the pupil from grade school to high school and from high school to college and university, courses in elementary branches of preventive and possibly applied medicine should be taught and should be made prerequisite to graduation. What seems desirable is that the man on the street and the mother in the home should have a more extended knowledge of first-aid remedies and preventive measures. Health reports should be as easily understood by business men as market reports.

In conclusion, the most important

things before the health educator today are believed to be: First, changing habits and inculcating a knowledge of health fundamentals in the adult population; and second, working out a thoroughly practical course of health instruction for our schools and colleges. These are the important elements of a health education campaign whether worked out on a national or a local basis. It is believed that a national program must result if the nation is greatly to reduce the number of its unfit in any short length of time.

Scientific Societies Meet

NINE scientific societies in joint session in Chicago, December 28 to 30, conferred on a wide range of topics—social, psychological, and legal—having a direct bearing on public health. This was particularly true of the discussions before the American Statistical Association, the American Economic Association, and the American Sociological Association. Albion W. Small expressed the spirit of the meeting when before the American Sociological Association he stated the opinion that the ultimate object of all scientific inquiry is public welfare.

A specific instance of how pure science becomes socially profitable was brought out in the address of Judge Hoffman of the domestic relations court of Cincinnati. Through mental, medical, and social study of cases com-

ing before his court during the five year period just past the scientific handling of delinquency has so far progressed that, beginning with January 1 not a single child in his jurisdiction will be incarcerated in a penal institution. Diagnosis and treatment through psychological clinics to be established is to be substituted for the punitive measures which in the past have everywhere begged the question instead of solving it, and progressively increased the need for institutions to house children who should never have been institutionalized.

The advantages of team work between the several social agencies were emphasized in the evening sessions when addresses were given by the presidents of the three societies named. The statistician's viewpoint of calculated inquiry was well brought

out by William S. Rossiter in his address on "An Adventure in Population." Henry R. Seager, president of the American Economic Association, offered his explanation for social phenomena in the economic forces which it must be conceded are the broadest single causative factor in wide fluctuations either in numbers or status of large masses of the population. Rational inquiry and rational remedy were developed in the presidential address of James P. Lichtenberger, representing the sociologists, whose experience in adjusting idealism to existing circumstances has resulted in a philosophy of opportunism which makes possible a working basis for essential reforms.

A significant study, discussed in advance of the published report, was offered by James H. Tufts of the University of Chicago, who, under the auspices of the Russell Sage Foundation, has made a study of the education and training for social work. This study divides itself into two lines of inquiry: (1) Accepting as fairly well defined a considerable central group of activities, how far may social work wisely extend to various specified border fields; and, more important, how deep shall it go in its exploration and its methods of treatment and prevention?

Stated in terms of education and training, the issue is, (2) Accepting as undoubtedly necessary a certain type of training for the fairly well defined agencies of relief, aid, and administration or oversight, shall the institutions engaged in giving preparation stop with this conception of their task, or shall they aim at so broad and thorough an education and training for at least a minority as shall fit these for the larger and profounder tasks which may be conceived under the analogy of social engineering or social statesmanship? Shall they undertake the study of the fundamental forces of human life, of the ultimate values of human welfare, and of the great institutions of human society in order to meet that larger responsibility which no other profession than social work at present seems to accept?

The meeting was full of interest. The program was exceptionally well planned by departments to bring out the special lines of inquiry that are under way. From the standpoint of original contribution the psychological workers seem to rank first, and their work has been particularly fruitful in correlating work that has heretofore seemed to stand in separate categories.

Epidemiology in Europe

THE Health Section of the League of Nations published in June, 1922, the third of their series of bulletins on Epidemiological Intelligence, containing a most interesting map of the epidemic situation in Europe during the first quarter of the year.

Of all the countries in Eastern Europe, Russia has suffered most from epidemics during the last four years. During this time about seven million cases of typhus and relapsing fever were officially reported without counting the figures for the Red Army. The culminating point was reached in 1919 and 1920 when 4,917,000 cases of typhus and 1,259,500 of relapsing fever were officially recorded.

It is stated, furthermore, that these figures do not represent the total incidence, and must be multiplied by at least two and a half in order to obtain an approximate picture of the situation. The cholera epidemic of more than 176,000 reported cases which broke out in 1921, proved the most deadly visitation for many years.

Typhus has not been stamped out in Esthonia and Latvia mainly because of the number of persons returned from Russia, and for the same reason a serious situation existed in Eastern Poland during the winter of 1921-1922. This was due partly to the inadequacy of the quarantine stations and partly to the fact that

many of the repatriated persons crossed the frontier through woods and marshes thus escaping any sanitary control.

Before 1913, cholera and relapsing fever were comparatively unknown in Roumania. Since then they have appeared with moderate extent and severity and have been controlled without great difficulty. Toward the end of 1916 typhus and relapsing fever assumed extremely serious proportions. Particular mention is made of the effect of relapsing fever in awakening latent tuberculosis. Two years later relapsing fever had completely disappeared and typhus was greatly diminished. Highly virulent scarlet fever, often fatal within two or three days, appeared as typhus diminished and died out as typhus reappeared.

Conditions in Turkey, Danzig, Transylvania, Bukovina, and Bessarabia have been quite satisfactory.

Influenza in pandemic form, which appeared in November and December of 1921, was synchronous with a markedly increased death rate over a wide area. Northwestern Europe appears to have suffered most heavily while the outbreaks in America, Asia, and Africa were for the most part mild in type.

General Science Instruction Applied to Health

An outline for class work, together with sample papers, pictures of maps and exhibits prepared by ninth grade public school pupils relating to the water supply system of Cleveland are presented in the May, 1922, issue of the *General Science Quarterly*.

Such an organization of local material for instruction in general science seems to be a very desirable procedure. The outline of study covers such topics as the history of the development of the local water supply; methods of filtration and distribution; consumption and character of the water used; and local sources of pollution.

Simple laboratory problems are included in the course of instruction, —tests for the hardness of water, construction of maps of the plan of distribution, charts of the fall in typhoid death rate, and the building of sample slow sand filters.

Visits to the local purification plants coupled with such a course of study and instruction teaches the pupil the fundamental facts concerning an important municipal health project and general scientific principles, and develops a community pride.

Indiana Tears Down Its Old Houses

By A. E. WERT, DIRECTOR, DIVISION OF HOUSING, INDIANA STATE BOARD OF HEALTH, INDIANAPOLIS, IND.

THE Division of Housing of the Indiana State Board of Health was put into operation on the first day of October, 1921, to administer the housing laws of 1913 and 1917 relating to the construction, alteration, and maintenance of tenement houses, and concerning dwellings or places of residence unfit for human habitation or dangerous or detrimental to life and health. Being a new division, it required much careful study and planning to get the work

the local building inspectors, architects, realtors, and builders. The result has been very satisfactory and shows that in most cases these agencies are anxious and willing to cooperate.

Local machinery for enforcing the law of 1917 was already a disciplined unit consisting of local health officers, health boards, sanitary inspectors, and county health nurses, already accustomed to similar branches of work designed to conserve public health and safety.

During the one year of the existence of the Division of Housing, the work has consisted of field inspections, enforcing and following up provisions of the housing laws, assuring local health officials of state backing and help, investigating actual conditions, handling and enforcing obstinate cases in which local officials have not been able to get proper compliance with their orders, ordering improvements in cases that have not been brought to their attention and securing photographic evidence of existing violations, these photographs being used in connection with educational talks and prosecutions if necessary.

The department has received full cooperation of various city authorities and health officials throughout the state and has investigated and remedied many cases that have been brought to its attention by county health nurses.

It is not necessary to travel very far without having bad housing conditions emphasized at almost every turn. to find people "housed" in shacks, stables, old cars, old store buildings, basement and garrets, and the numerous improvised tenement and apartment rooms. None of these places are fit for homes and there is no excuse for the existence of such places in the wealthy state of Indiana. Mrs. Albion Fellows Bacon has said, "Bad housing piles up social wreck-

Lawrenceburg, corner Short and High streets; cesspool in rear of apartment building: full to top, contents of which were pumped into the street gutter; inspected July 10, 1922; condemned July 15, 1922, cleaned, repaired and covered.

properly started and this planning was made much easier by the thoughtful study and digest of the many reports of work accomplished by Lawrence Veiller of the National Housing Association of New York, by Edwin H. Sands, State Housing Commissioner of Iowa, and by Bleecker Marquette of the Cincinnati Better Housing League.

Indiana has its full share of tenement owners who would never move to improve living conditions for their renters except under compulsion of law. The dark, ill-ventilated rooms and halls, box stairways, inside rooms, want of yard space, lack of sanitary equipment, no fire protection, no privacy, overcrowding, and consequent breeding of disease and immorality are some of the things which the enforcement of these laws will prevent.

The law of 1913 required much pioneer work in securing cooperation of

Bloomington, Ind., Morton street; seven two-room apartments in frame shed over garage; concrete garage adjoining built tight against the frame building cutting off all light and ventilation except the two front windows shown and two similar windows at the rear end; rent per each apartment, \$8.00 per month; inspected October 27, 1922; condemned and ordered vacated November 1, 1922; vacated November 15, 1922; no water and no toilet.

age faster than churches can evangelize, faster than schools can educate, and faster than doctors can

The first annual report of the Division has been prepared and gives in detail the work accomplished during

Aurora, Ind., 204 Johnson street, building ready to collapse; contained one family at \$4.00 per month; inspected July 20, 1922, condemned and ordered razed by August 15, 1922; family vacated August 1, 1922; house razed and new building on the property about ready for occupation.

cure." There is not much difficulty in locating the sore spot in any community.

The personnel of the Division has consisted of the director, assistant director who is also chief inspector, and one follow up clerk.

the past year. Among the data given would be found the above items of especial interest.

Numerous complaints received from all parts of the state were also investigated and remedy suggested by the state division of housing.

Smallpox in London

BY OUR LONDON CORRESPONDENT.

LONDON has been threatened with an epidemic of smallpox.

Most of the cases which occurred were in the suburban district of Poplar in a poor neighborhood. There were forty or fifty cases and a few deaths and the lay papers frightened the inhabitants of London sufficiently to impel a large proportion of them to be vaccinated at once.

With respect to the effects of vaccination, many examples of its efficacy have been brought forward during the past few weeks. Recently certain opponents of vaccination quoted the ex-

perience of Nottingham in the year 1921 as favoring an anti-vaccination policy. However, Dr. P. Boobyer, Medical Officer of Health of Nottingham, has shown that this state is altogether at variance with the facts. The actual state of affairs in Nottingham during the epidemic of smallpox, February 1921 to January 1922 was this:

About half of the children in the city had been vaccinated. Not one of these contracted the disease. There were no cases of smallpox among children under ten years of age who had

been vaccinated. Among the unvaccinated children under ten years of age, there were fifty cases of smallpox. There were no cases of smallpox among vaccinated persons under thirty years of age, while for the same ages there were a total of eighty seven cases among the unvaccinated persons. Indeed the experience of Nottingham, far from being against a vaccination policy, is held by medical authorities to be one of the most remarkable pieces of evidence in favor of vaccination. It most assuredly points to the fact that the vaccinated child is protected against smallpox.

Some Census Figures.—It is shown in the Register General's Blue Book issued a short time ago embodying the results of last year's census that in Greater London area there are more than 500,000 more inhabitants than there were ten years ago, the present figure being 7,480,201. The most remarkable feature is the preponderance of women, the numerical excess over males now being 341,365, an increase of 72,362 over 1911. Of course, this is partly due to war losses among the male population. Incidence in sex proportions, however, lies mainly in their incidence on the marriageable population. The ratio of unmarried females per one thousand unmarried males has increased from 1,138 to 1,287 in the age group twenty to twenty-nine and from 1,413 to 1,886 in the age group, thirty to thirty-nine. In regard to housing the average number of families per occupied dwelling has increased from 1.51 in 1911 to 1.50 in 1921. Whereas the number of private families has increased by 9.5 per cent in that period, the growth in the number of occupied dwellings has been only 16.1 per cent.

Need for Clean Food.—There is great need in this country for laws and regulations with respect to clean food. Milk is exposed in a most careless manner. It is a common sight in London to see milk being drawn from a can in the street. This unclean and dangerous custom is prohibited by law in America. Meat is frequently carried through the streets of London uncovered and is displayed in various parts of the city outside butchers' shops where it is accessible to contamination by flies and dirt. This custom is not permitted in America. The law as to canned foods here is lax and a pure food law greatly needed.

The new Public Health League of Kansas City has a section to carry on locally the work of the American Society for the Control of Cancer.

Federal Standards Urged for Food Inspection*

By E. H. PAPE, M.D., HEALTH OFFICER BERKELEY CALIF.

WHEN we speak of food inspection we usually think of meat or milk inspection, with possibly the most emphasis placed upon milk inspection. This is probably because milk has in a number of cases been the agent for spreading disease and epidemic. But the disease carrying properties are not the only things to be considered in food inspection,—there is the wholesomeness and the food value to be considered also. In meat inspection we are accustomed to think of slaughter-house inspection, antemortem and postmortem inspections. This is good but it does not insure that the consumer will receive the meat in a wholesome condition or prevent the retailer from exposing the meat on a counter until it becomes tainted and decomposed, then make stews or corn beef out of it, or, as is commonly done, grind it up into hamburger and weenies where the good is mixed with the bad and is not easily detected.

Then there is the question of tuberculous fowls and the diseases of fish on which very little has been done and which do not come as a rule under the Federal or state meat inspection. The meat and milk is, however, a very small portion of the food supply. The molding, fermenting, and souring of fruits and cereals; the infesting of flour with weevils, grubs, and moths that find their way into the bread and other bakery goods; the rice weevil that infests the macaroni and noodles, the rice mites which are so small that they are usually overlooked in the rice; these, and myriads of other things having to do with food inspection, are mentioned merely to show the prospectus of adequate food inspection.

It has been said by very good authority "that history is a reproduction of geographical laws, that character is a function of latitude, and that a man is what he eats." It is certainly true that a man cannot be his mental and physical best if he is not well, and he certainly cannot be well, if he does not have good, wholesome food. It has been a long established fact and has been proved both by animal and human experimentation that a well nourished subject will resist disease and the same

subject when poorly nourished will easily contract a given disease. When we consider the delicacy of the intrinsic mechanism of the digestive tract, or the sickening effect of the psychic sensation that is transmitted through the vagus nerve at the thoughts of eating or smelling something unwholesome, or in the mildest form the depression of auto-intoxication caused by eating bad food, we begin to understand something of the value of food work, and when an outbreak of food poisoning occurs such as that at Kewanee, Ill., some few years ago when several hundred people were stricken on the streets and in their homes and doctors from the surrounding country had to be drafted to take care of the sick, we see what food inspection can prevent.

Town Judged by Food

Since the health and wealth of a community depends upon its food supply, much attention should be given to food work. It is too often thought that the work of the health department has to do only with contagious disease. Important as contagious work is, it deals with only a very small per cent of the population while food work deals with the whole population, in fact, the workers and producers on which the community exists. A city or community is often spoken of or is rated on the basis of its food conditions. Travelers usually stop and transact their business in towns or cities which have good food accommodations. It is the best advertising that a town can have.

Food conditions are a matter of education, not legislation. Legal means should be used only when all other means fail and then as a means to enforce the ordinance and command, and not demand, respect for the department. This is not to infer that the department should be lenient. On the contrary, the department should be firm and consistent. Since food inspection is a matter of education, it demands a leader or director, and such direction should come from the department conducting the inspection. The inspector should be well trained and well informed about all matters having a bearing upon his work. He should have a good personality, be a good judge of human nature, and above all have good self control. He should be able to edu-

cate the public on matters of good food. For instance, some people have the idea that meat should be well hung until it is covered with mold or what they call well ripened in order to be tender. They think that when the aerial hyphae is wiped off that the mold has been disposed of, but when it is explained that the plant is a saprophyte and that its mycelium reaches deep down into the tissue of the meat where it takes up the decomposing substances and that the plant cannot live on good food but lives only upon decomposing or rotting substance, and that moldy food stuffs will readily kill chickens and cattle, they soon make up their minds that they do not want moldy foods. The courts have ruled in this respect that those who want to eat such foods can do so but such foods cannot be kept in any public market where it is likely to be sold to the general public.

Inspection must be done locally and the inspector must be on the job and make frequent inspections. A state inspector cannot do this. Most people are willing to clean up and sell good food if everybody is made to do so. This has been proved by the largest and best establishments that they gladly welcome inspection and are willing to use the very best food obtainable so long as other people are made to do so, but just the minute inspection stops, they immediately begin to use anything that can be used in order to compete with some of their competitors who are less scrupulous.

It is human nature to be more particular about the way the shop is kept or the business is conducted if the proprietor knows that an inspector is on the job. The score card has long been considered a strong factor in inspecting work, and particularly, if the scores are published in the local papers. This creates a great deal of interest and enthusiasm if everyone is convinced that the inspection is fair. The greatest need at the present time is for a Federal score card that would serve as a standard score card for all cities. Competitive scores could then be arranged which would do for food work what interscholastic contest has done for collegiate athletics.

Late in the year 1921, Berkeley adopted a comprehensive ordinance

*Presented before the health officers section of the League of California Municipalities, September 21, 1922, Palo Alto, Calif.

calling for the use of the United States Public Health score card and used the same for all kinds of food shops excepting meat. It was surprising to those connected with the work to find that most of the shops fell below score and many were in

such condition that scores could not be made. After considerable effort and diligent working, fairly satisfactory scores were obtained. It was also a surprise to see how quickly the different firms or shops raised their scores after the system was once es-

tablished. We feel that we have been able to accomplish a great deal in a short time by the use of this system, and wish to have other cities join us in order to establish a standard score card and method of scoring.

Public and Private Health Agencies*

An Inert Public Is the Chief Obstacle to Effective Health Work

By C. V. CRASTER, M. D., HEALTH OFFICER, NEWARK, N. J.

FORMER discussions upon this subject have revealed a variety of opinion as to how the public shall best be served by health agencies, both official and non-official, in order to promote the welfare, safety, and health of its individual members. The chief aim of health workers to serve the public interests is, however, frequently lost in a cloud of lesser interests.

Experience, that most terrible of taskmasters, has taught mankind through the ages by pestilence, plagues, and famine the definite truth that man to save himself must first have knowledge to understand the reason for his sufferings.

It is this mass of historical experience of the written word of suffering that has been the most important asset in our public health superstructure of today. The foundation of this new science being basically historical, it is important to know the mental picture of man's reaction to the restraints of authority if we wish to determine the best means of applying modern principles of public sanitation and hygiene.

The care of community health must necessarily appear a changing problem. We grow into what we find will meet our everyday situation, so that the principles that formerly guided our ancestors would appear to us outrageous if applied to our modern situation. It was the simple and unsalable facts of common welfare and decency that produced the public opinion which led to the passing of health laws and the appointment of boards of health to enforce them. Feeble though the powers of the early boards of health were, public opinion supported them when epidemics menaced public safety. The functions of the old boards were primarily the exercise of police powers directed to-

wards the attainment of a minimum standard of cleanliness around buildings and upon public streets.

As new facts were garnered upon the cause of disease, new laws were passed to be more or less generally enforced as community measures to secure the minimum standards of hygiene and sanitation of every individual. This was primarily true of contamination of water supplies, of food and milk supplies, and of sewage disposal. Not many years ago every household had its own cow and private cesspool and well conveniently located for contamination.

The Issue Broadens

The citizen having surrendered his individual right to do what he pleases so that his neighbors might benefit as a unit, only within the last fifty years has he had time from his building, his harvesting, and his wage earning to observe and think upon those questions of national health which have been brought up to him for discussion and intelligent comment. It is this new era of leisure to think that has enabled great nations to make vast strides in national development. This era made possible the adoption of vaccination and the acceptance of the doctrine of Pasteur, of Lister, and of Koch.

Having mastered, so to speak, the rudimentary principles of sanitation and disease prevention, there has come a time when the problems of health to be solved are so huge, and apparently insoluble by reason of the inert mass of lack of understanding among the people, that the old weapons are useless. New ones have to be forged. The application of sound principles of modern health practice is everywhere opposed by the inertia of ignorance, of diffidence, and even of actual hostility by certain classes of every community.

It is easy to teach hygiene where

comfort and ease exist and when the pressure of want does not interfere. It is an entirely different thing to apply such principles in squalid tenements and overcrowded rooms, and yet it is hither our efforts to improve conditions must be directed. It was the recognition of the need of education, for publicity, and the placing of public health propaganda before the people in an attractive and simple manner that has brought forth in America the organization of the various unofficial health agencies. It has been suggested that the number of these agencies is a direct reflection upon the work of the official agencies. This, however, is a distorted view and one not held by those familiar with the social and economic problems that face all health organizations. In contrast with the freelance outlook of the private health agencies, the health board is the official agency of the people and by its constitution cannot be adapted to meet all the needs of modern health activities. Such police powers as it may exert are limited by public opinion. Its activities are influenced by various local needs and the restrictions of inadequate appropriation.

However broadly conceived, its policy is small in scope as compared with the ideal requirements of health activities. One of the greatest evidences of a public awakening from the "let George do it" attitude, is the formation of the private health agencies. Although sentiment and charity have in the main promoted such agencies, the results achieved will necessarily depend upon the quality of their publicity and propaganda. The feeling of community effort is one that appeals to many people, and indeed the success of these agencies in focusing public attention upon health problems has been a wonderful incentive to fresh endeavor on the part of the official agencies. What then shall

*Reprinted from the Monthly Bulletin of the Department of Health, Newark, N. J.

be the functions of the two classes of health agencies will depend upon the very definite path blazed by each in the progress towards health ideals.

Analysis of Function

If the various activities of health departments are arbitrarily analyzed by a simple method of scoring, it will be seen that certain divisions of work are capable of definite and different means of application. Thus with a minimum of six points the distribution may be made as follows:

Field	Law Enforcement	Publicity	Education and Propaganda
Sanitation	.. X X X X		X
Contagion	.. X X X X	X	X X
Tuberculosis	.. X	X X	X X X
Child Hygiene	... X	X X	X X X
Food and Drugs	... X X X X X	X	X
Veneral Disease	.. X	X X	X X X
Mental Hygiene	.. X	X X	X X X
Vital Statistics	... X X X X	X X X	

The principles of sanitation and hygiene are very generally accepted today, so that there will be very little need of publicity or propaganda especially in our cities whenever there is need of law enforcement for violations of the sanitary ordinances. This does not apply, however, to the more rural districts. It is for this reason that there are few private health agencies that specialize upon this division of public health.

The principles of contagion are generally accepted, so that law enforcement is the real need in this division.

The suppression of tuberculosis is now well recognized to be within our view. This can only be accomplished by a wide publicity by general education and propaganda in all classes of society.

Child hygiene is now a well recognized health board activity for the reason that its propaganda and publicity are only possible by direct contact with mother and children at or before birth. This cannot be effectually carried out by private agencies.

The division of food and drugs is almost entirely a matter of authority and effectual supervision, and of law enforcement; little publicity or education is needed among the general public.

Veneral disease, only of late years accepted as public health activity by the official bodies, is still in need of a vast amount of publicity and education. It is still uncertain how this can best be accomplished. During the

last war the government through its army, medical and United States Public Health departments entered into active competition with the private agencies in effective publicity and education in this field. This division of public health may best be served by activities directed along the lines of attractive and simple publicity and education.

Mental hygiene, the newest of our health divisions, will require continuous propaganda to place it in the important place it deserves as a public health activity.

Vital statistics, that is, the use of material gathered from reports of births and mortality, and their authority will depend upon accurate reports made in conformity with state and city laws.

It is evident, therefore, that for many important items of public health a wide and general publicity and education will be a necessary requirement for bringing these subjects before the public. The official health agency cannot hope to command the funds necessary for aggressive action in any one of these divisions. The very diversity of its activities makes it impossible to direct any great amount of its funds for publicity and propaganda as extensive as that estimated as necessary for modern purposes.

Prepare the Soil

Here is manifestly the rôle of the private health agency. It can popularize by publicity and by education the accepted principles and truths of its own particular health line, seeking to put these in such a way before the public that they will become more or less accepted principles of every day life. Certain private agencies have in the past lost time and prestige in using their subscribed funds for purposes usually regarded as administrative and in seeking to maintain this stand when official agencies have developed activities along similar lines of work. This is particularly true of certain clinical activities and field work, logically true functions of boards of health. The bringing of health education to the home should be in the hands of employees of health boards, who alone have the legal authority of the open sesame and whose purpose in entering such homes is absolutely "communistic," if I may use such a word. The public health field work carried on by private agencies, particularly insurance companies, is no doubt useful in a wide sense, but nevertheless is difficult to separate in the public estimate from business propaganda and loses much of its

force from this very association.

If during a fight against any communicable disease a public clinic for advice and treatment is necessary, this should undoubtedly be in the hands of the official health agency. It alone can bring to bear all the forces of government to eliminate contagion from the community. A strong point in the suppression of most of these diseases also is the authority to invoke the powerful arm of the law where the public safety is menaced by carelessness or outright criminal actions. The usurpation of official administrative function by private health agencies is a fruitful cause of loss of efficiency and an undesirable feeling of competition in health activities. A private health agency which is carrying on administrative health functions as a result of the neglect of official action is necessarily a stop-gap and should function only until the official agency can be galvanized into action. Indeed, a good part of the education and propaganda of such an agency should be directed toward this end. The private agency generally fails as an administrative machine because of its lack of authority to act as a law enforcement department.

The present position with regard to the division of responsibility for the control of tuberculosis in many of our states has developed a sound arrangement for the cooperation of public and private agencies through the dispensary clinics and the follow-up work by field nurses and the erection and maintenance of sanatoriums in state, county, and local health activities, in which all the necessary clinical work and treatment is provided for. The publicity, education, and propaganda upon the suppression of tuberculosis have been gradually taken over by the national and state anti-tuberculosis leagues who, by means of the sale of Christmas seals and other collections, provide the means to carry on in the press a wide publicity campaign directed along the lines of personal protection against infection and the necessity of providing sufficient sanatorium beds by the local authorities. Education in the schools is also a strong point in this campaign against tuberculosis.

The official agency should be in the position of a good commander who welcomes all his allies, regular or irregular, who will aid him in defeating the common enemy. Cooperation to fight disease should be mutual, the official agency recognizing the popular appeal of and giving due credit to those private agencies doing their part in popularizing the fight for pre-

ventive medicine and public hygiene. On the other hand, the boards of health should be the official headquarters of all health campaigns, guarding jealously and using judiciously all those police and administrative functions with which they are endowed by law. The influence of a well organized board of health with a competent and trained health officer is incalculable, giving to the public that security of public welfare which the publicity and propaganda of the volunteer agency usually help to emphasize.

Active and incessant publicity far beyond what the official agency can hope to accomplish will be necessary for many years to come. Volunteer agencies can alone help to make public the voice of the poor and the socially enslaved. When all is said and done, however, there is no one, who is familiar with the writings of Jacob Riis, of Robert Hunter, or of General Booth, or who has had a first hand knowledge of social conditions in our large cities but will confess to the total inability of health agencies of any kind as at present constituted to

make much impression upon the inert mass of people who are physically and mentally unable to respond to the teachings of modern health principles. Only social and economic improvement will raise the curtain of gloom. "Sickness," says Hunter, "assumes a new and more terrible meaning when one realizes that the mass of wage earning families are pathetically dependent upon some one person's health. Anyone familiar with the poor knows with what grim determination half sick workmen labor under this heavy responsibility." How futile seems to be our health propaganda in the face of the misery of the laboring classes.

Promised Land of Health

Great improvements in public health will wait upon better housing, better food, more rest, and recreation for the individual worker. "The poets and prophets," says Ruskin, "though they have told us much about the life that is now. They have had—they also—their dreams and we have laughed at them. They have dreamed

of mercy and of justice, they have dreamed of peace and good health, they have dreamed of labor undisappointed and of rest undisturbed; they have dreamed of fullness in harvest and overflowing in store; they have dreamed of wisdom in counsel and providence in law, of gladness of parents and strength of children and glory of gray hairs. And at these visions of them we have mocked and held them for idle and vain, unreal and inaccomplishable." Public health can not disregard the real social problems which retard its final success and attainment. Within modern times the fabric of this new temple of healing has been supplied from nearly every science and art in the quest for material. It has become a science so intimate and far reaching, with ambitions so altruistic and benevolent that the public cannot be blamed for being somewhat loth to accept its seemingly visionary ideal.

Only by a wide tolerance of every type of public health effort to improve our people may we hope to reach even a part of our promised land.

Detroit Corrects Postural and Foot Defects

POSTURE and foot conditions exert an important influence on health. They are responsible for many ills, for fatigue, for slovenly personal appearance, for inefficiency. The Detroit Public Schools, realizing the dangers of faulty posture and weak feet, have made their elimination two objectives of their individual gymnastics plan.

"We put so much stress upon good posture in our schools because it is one of the fundamental health habits," writes Augusta H. English, assistant supervisor health education, department of individual gymnastics, in *City Health*. "When the body is used rightly or in the normal state of

health, there is the least possible strain or friction. In good posture the figure should express strength and poise without rigidity and tenseness. The trunk or body being given its greatest length, there is ample space in the upper part for heart and lungs to function properly and for organs of the abdominal and pelvic regions to do the same. This is impossible if the space in which they lie is constricted. Good posture is a position of readiness and efficiency for action, and besides promoting health gives the impression of vigor, alertness, energy, and dignity. It is graceful and pleasant and usually indicates self-control and self-respect.

"If the question is asked whether a boy or girl is less healthy for being round shouldered the answer is that he may or may not be, but while one boy or girl with round shoulders, which carries with it the lessened use of upper ribs in breathing, may escape serious consequences, another may not. One child may go through life with a mild form of lateral curvature of the spine and not suffer but hundreds consult physicians every year because of this condition. Many an individual wears improper shoes without bad results while hundreds pay with flat feet and suffering. It is wisdom to avoid these dangers."

The department of individual gym-

Fallen arches before gymnastic work was undertaken.

nastics prescribes a regime for the child with postural defects—such as hanging on bars, standing with head back, chest up, lungs filled with air, and other exercises tending to correct his defect. Orthopedic treatment is accorded the pupil with postural or structural scoliosis.

The department aims also to help eliminate cardiac weakness by cooperating closely with the physician and giving exercises to strengthen the heart and to aid in increasing the child's resistance to progress of the disease.

A common defect for which the department has a definite procedure for correcting is weak feet or fallen arches. A foot print is made of those pupils giving evidence of foot weakness at the examination and three months later, after a series of exercises have been taken, another foot print is made to determine progress. Five prints representing a good type of foot and working back to the fallen arch are exhibited and the child is stimulated by comparing his own foot print with this scale.

The work done in individual gymnastics is largely preventive and deals first with the student individually and then as a member of a small group. Physical examinations are given in the first and fourth grades of all sixth-grade schools, and in the third and sixth grades of all eighth-grade schools. In the spring a second examination will be made of all pupils selected for special exercise work.

The department is carrying on work in twenty-five schools including elementary and intermediate, and the plan is to increase the number as the staff of teachers is increased. The class period is thirty minutes and at-

tendance in each class is limited to twenty. The schedule of each teacher includes two schools, one of which is

visited three days a week, the other two days. A small number of teachers give whole time to one school. The department also supervises the exercise work in the schools having open-air rooms and the class at the Russell school for children having organic heart disease.

The cooperation of the children has been of the best. They are interested in directions by which faulty conditions can be improved and are eager to get "points" on the health rating cards. Through this work of reclaiming the young, many will doubtless be saved from serious defect in later life.

Citizens of Baltimore county have organized a public health association. A constitution and by-laws were adopted and fifteen district directors and six directors at large selected. The new association will continue the work heretofore carried on by the Baltimore chapter of the Red Cross.

How New Zealand Saves Babies

FOR a considerable number of years the Dominion of New Zealand has had a lower infant mortality rate than any other nation in the world. Australia, Norway, and Sweden have been her nearest rivals in the competition but at no time since 1910 have her records been equalled. Next have come Switzerland, Netherlands, South Africa, Denmark, England and Wales, all of these for the most part have been in the lead of the United States birth registration area. The present impetus in this country under the stimulus given by the Sheppard-Towner Act, lends especial interest to the study of methods and conditions entitled "Infant Mortality and Preventive Work in New Zealand" which has just been issued by the United States Department of Labor through the Children's Bureau.

For the period 1872-1874 in New Zealand the number of deaths of infants under one year of age was 105.9 per 1,000 live births. From 1875 to 1879 the rate was 101.5, or practically the same as that of the United States birth registration area as late as 1916. By this latter year the New Zealand rate had fallen to 50.7, or half its former size. In 1919 it reached the new low level of 45.3.

From 1872 to 1905 a rapid and continuous decrease in the rate of infant deaths from epidemic diseases and tuberculosis took place,—a de-

crease which the report attributes to the combined influence of improved sanitation, extension of the powers and improvement in the administrative methods of the public health authorities, and increase in the professional and popular knowledge of the best methods of maintaining health. The death rate from these causes is still decreasing and by 1905 its reduction had already brought the New Zealand infant mortality rate to a point lower than any yet reached by the United States birth registration area.

The report points out that while reductions are more easily secured when the initial rate is high than when it is low, during the period following 1905, the decline in the infant mortality rate of New Zealand, instead of becoming less pronounced, was strikingly accelerated.

In 1907 there was formed in one of the cities of an organization which spread throughout the Dominion and become known as the Royal New Zealand and Society for the Health of Women and Children. By 1919 it was reaching through its infant welfare centers more than one-fourth of all the babies born in New Zealand, or probably the great majority of those most in need of such care. All classes of society avail themselves of the services of the specially trained nurses employed by the society. The services are not regarded as being on a chari-

table basis. The society, which maintains a special baby hospital for the training of the nurses, supplies a weekly column in the newspapers, maintains clinics and home visiting service, is declared by the Children's Bureau report, to be undoubtedly the most important influence in the reduction of the infant mortality rate.

The government of New Zealand, in addition to its cooperation with the Royal New Zealand Society for the Health of Women and Children, main-

tains six state maternity hospitals; trains maternity nurses; licenses and supervises all public and private hospitals; and regulates homes in which children under six years of age are boarded apart from their mothers. In 1904 the government required the registration of midwives and formulated a standard course for their training. Cottage hospitals have been established in the remote districts and nurses appointed to work in these fields. Physicians have been sub-

dized to take up practice in regions where otherwise they would have difficulty in making a living.⁹

Birth and death registration in New Zealand have been excellent for a long period of time so that an accurate measure of progress is possible.

This report by Dr. R. M. Woodbury is based on material obtained by the author during a recent visit to New Zealand. It pictures a condition that should make all other nations of the world envious.

Sanitary Considerations of Swimming Pools

CLEANLINESS is essential to health. Sanitary science has evolved out of the organized work undertaken in the solution of specific problems in securing and maintaining cleanliness under any and all conditions. The minimum sanitary standards have gradually been incorporated into hygienic codes which represent the basic conditions of public health. Sanitary codes are constantly subject to revision according to the changing habits of a people.

Just as adequate ventilation has become an engineering problem under the complex conditions of modern life, so does water purification encounter heretofore unconsidered forms of pollution requiring new mechanical and chemical means to combat. The old swimming hole with its constant motion and perfect aeration afforded every advantage of recreational activity without carrying the concomitant menace of contamination that attaches to the public bath in urban communities.

Nor did the earliest indoor pools constitute the varied sanitary problem represented by the swimming pool today. Available in the past only to the fastidious members of college gymnasiums or exclusive clubs, the number of bathers who patronized the tank in a month would scarcely equal the number of bathers in one of our modern public swimming pools in a single day. With this increase of patronage the wasteful and costly method of putting the pool out of service for a slow process of draining, cleaning and refilling with heated fresh water would be as impracticable as to rely upon the hygienic habits of the individual bather to hold himself to safe and hygienic practice in the use of the public bath.

Certain hygienists hold that the tanks of penitentiaries, jails, asylums, hospitals, and charitable institutions should be replaced by showers. This

overlooks the therapeutic value of the bath and its recreational aspects, and evades the problem of bath sanitation rather than meets it. All public bath houses should be arranged so that the bather will be compelled to pass under a shower and wade through water before entering the pool. The water of public bathing pools should be examined bacteriologically by the local health officer, and methods of sterilization utilized when advisable. Attendants in charge of bathing pools should be instructed in methods of detecting cases of infectious disease and should be required to exclude from the pool all persons showing evidence of infection.

Bathing should never be permitted in polluted water. Beaches in the vicinity of contaminated water should be placarded as dangerous. The indoor pool presents specific problems of sanitation that can be met by the routine observance of prescribed conditions. It is evident that measures of personal hygiene must be supplemented by attention to the tank itself, and to the water. Many methods have been recommended for the disinfection of water. In the application of ultra-violet rays to the disinfection of water the water is re-circulated through a chamber in which the violet ray is generated with a mercury

quartz light. Twenty-six watt hours per cubic meter of water will serve to disinfect six hundred cubic meters of water in twenty-four hours. Under some conditions the water so exposed will be rendered sterile. Impregnation with ozone is also utilized, but the sterilization of water by chemical means is the usual method and of the various chemicals recommended for this use, chlorin, carefully regulated in accordance with the amount of organic matter in the water, is the most expedient. The principle of the several types of chlorination systems is about the same. Chlorination is usually obtained through the use of hypochlorite of lime, or by the use of chlorin gas. If chlorination is to be used in conjunction with slow filtration, the chlorin is usually applied directly to the water leaving the filters.

Pool sanitation is not identical with water purification. Chemical treatment of water, immediately effective in action, will actually sterilize the walls of the pool and the piping throughout the recirculating system. Mechanical means of removing the sediment from the bottom of the pool, mechanical filtration, and re-circulation of chemically treated water combine to meet the requirements of the situation. The efficiency of a mechan-

Diagrammatic picture of re-filtration system for swimming pools: (1) Pool suction cleaner connection ten inches below water line when pool is full; (2) Y body hair strainer with blow-off cock and removable strainer cap; (3) Centrifugal pump mounted on cast iron base and connected to motor; (4) Motor with flexible coupling; (5) Confluent feed or alum pot used also to admit sterilizing solution to filter; (6) Quartz type water filter for exclusive use of swimming pool; (7) Sight water glass for sampling water leaving filter; (8) Water heater pressure coil pipe for low steam pressure; (9) Sterilizer equipment connected to re-circulating line.

Sanitary installation and routine inspection should make the health conditions of the swimming pool as nearly automatic as possible. Scientific considerations reduce the cost and increase the efficiency of public health requirements pertaining to public bathing facilities.

ical filter depends upon the kind and amount of coagulant used and the method of application.

Convenience and economy of operation and washing are points to be considered in installations. Bacterial efficiency of the average mechanical filter averages between 43 and 61 per cent. The best obtainable bacterial efficiency is around 98 per cent. Mechanical filters should remove between 60 and 70 per cent of organic matter. Cleaning of the filters is usually accomplished with filtered water.

An efficient re-circulating filtering system must include a suitable strainer, pump and motor, filter and heater, and a practical system for sterilizing the water. In the installation shown in Figure 1 two outlet connections located in the deep end of the pool are connected with the pump suction. When the pump is in action the water is taken from the deep portion, is filtered, subjected to chemical action, and returned to the pool through two inlets in the shallow part of the pool. The arrangement of the re-circulating fittings is such that all the water is withdrawn and treated every twenty-four hours. Hair, lint, cuticle, and foreign materials which find their way into the pool can be removed by suction cleaning, which takes this burden from the filtration system and reduces the difficulties of cleaning the filters. In this manner the water in a swimming pool can be effectively purified for an indefinite period without a complete emptying of the pool, a sufficient amount of water being permit-

ted to enter the pool each day to take care of the waste from overflow, splashing, etc.

The principle and general construction of all pressure filters differ in but two important mechanical details, (1) the strainer system, and (2) the filtering material. Strainers insufficient in capacity or complicated to clean become clogged, and the imperfectly filtered water retains sufficient organic matter to produce odors that require a complete overhauling of the system. The strainer should be sufficiently fine to prevent the passage of even the finest of filtering materials, and the piping so planned that the flow cannot be obstructed by these particles. Filtering material from ground white quartz, chemically pure to within a fraction of 1 per cent, removes all particles in suspension in the running water. The filter is cleaned by a reversal of the current, and the filtered impurities are washed from the top of the filter bed directly into the sewer. The washing operation is accomplished by simply shifting a lever. After the water leaves the filter and just before it is returned to the pool it is chemically treated.

An installation of standardized use in a gymnasium or for athletic contests is twenty feet wide by sixty feet long. Such a pool with a graduated bottom 7 ft. 6 in. at the deepest point will contain around fifty thousand gallons of water. Suitable construction for such a pool is a concrete wall ranging in thickness from twelve inches at the top to eighteen or twenty

inches at the bottom, the whole to be thoroughly treated with water-proofing and tile. Entirely around the pool near the top is provided an overflow or gutter drain. This marks the high water level. The main drain at the lowest point in the pool is utilized only when the pool is to be completely drained. Re-circulation is accomplished through the two sets of openings previously described. The approximate cost of building such a pool is about twelve thousand dollars. The mechanical equipment necessary for circulating, filtering, sterilizing, heating, and cleaning will represent an additional outlay of something like twenty-five hundred dollars. The expense of operation will naturally be much less in recirculating systems than under the old methods of emptying, cleaning, and refilling the pool. So have newer methods of sanitation taken care of the hygienic features essential in the public bathing pool.

Low Mortality from Dengue Fever

While there were more than 150,000 cases of dengue or "breakbone" fever in Texas during the summer months of last year, little or no mortality resulted according to medical directors of insurance companies of the state. Some death claims were paid by insurance companies as a result of complications from dengue fever, but so far as could be learned there were none from dengue pure and simple. The malady has been prevalent in Texas for years and this past year it merely showed up in the larger cities and appeared to be more noticeable because of the publicity given it. The victims were rarely confined to their homes for more than a week if they suffered from nothing more than an attack of "breakbone" fever.

According to the *National Underwriter*, many insurance companies reported no claims paid for uncomplicated dengue, but a considerable number of claims were paid for pneumonia and other diseases that were thought to be complications. The health insurance companies paid many claims though most of them were small. It is stated that health officials report three deaths from dengue in ten thousand cases that occurred in and near Dallas.

Such an occurrence suggests the need and value of morbidity statistics now collected by those cities and communities that are in the front rank of participants in the public health movement.

The Heart in Medical Selection

THE role of diseases of the heart and blood vessels in denying application of life insurance as well as in the mortality of accepted risks is of the greatest importance. In a total of more than eighteen thousand declinations by the New England Mutual Life Insurance Company 52.4 per cent were due to abnormalities of the circulation, and in a total of nearly 33,000 deaths 32.5 per cent were caused by cardiovascular disease.

From the standpoint of the company issuing life insurance it is highly desirable to be able to distinguish among applicants those who are seriously impaired and those who are not. If such procedure were possible it would protect the company from accepting bad risks and also be of value in aiding applicants with minor cardiac involvement in securing insurance.

It is reported in *The New England Pilot* that Dr. H. M. Frost of the home office of the New England Mutual Life Insurance Company is attempting to develop a method by which an examiner may determine whether applicants with abnormal heart signs are seriously impaired. The apparatus consists of a compound pressure gauge and spirometer. The

individual to be examined is required to perform various acts, such as holding a full breath, expelling the breath as far as possible, blowing and inhaling against the gauge, and blowing to complete capacity through the spirometer. It has been noted that in the course of such steps, the systolic blood pressure develops a surprising degree of fluctuation. "One hundred individuals—normal, as far as could be determined—were subjected to the test in order that a normal standard might be decided upon for working purposes. At the same time, about thirty individuals, who presented abnormal heart signs, were subjected to the test with results which suggested that it gave some indication of the condition of the heart and blood vessels." Though it requires considerable skill and experience on the part of the examiner to follow the rapid fluctuation in the blood pressure, the test is easily applied. It also has the advantage of causing no apprehension on the part of the applicant.

It is planned to extend the use of this test to other agencies for the purpose of obtaining a sufficiently large series of cases to determine its practical value.

periods." Such children can be taken care of effectively in any open air schoolroom with other children suffering from divers conditions, Dr. Schmidt asserts. They may even take exercise with the other children providing the physical culture teacher is instructed to watch for symptoms signaling cardiac distress.

In order better to study the cardiac child and to demonstrate the efficacy of the fresh air treatment, the Detroit heart clinic committee segregated a group of twenty-eight children at Russell school in an open air room furnished with Kalamazoo chairs. Aside from their regular study, these children receive one-half hour of graduated exercises with dumbbells under the supervision of a competent teacher twice each day. For nourishment they receive milk and graham crackers in the morning and afternoon of each day, following which they are required to rest in their reclining chairs for a period of about half an hour. Many fall asleep and are not disturbed, waking of their own accord.

Exercise control of these children outside school hours is a serious problem. Many confess that they take strenuous exercise outside of school. Supervised exercise, however, has proved of great benefit to the children improving their heart condition and physical appearance, and increasing their weight. The fear that many physicians and parents have in regard to exercise for cardiac children is unwarranted and based on the old conception that heart failure was due to a mechanical factor. Infection rather than exercise is to be feared.

The magnitude of the infection factor is seen when a large proportion of the 2,000,000 sufferers from heart disease in the United States give a previous history of rheumatism or chorea. As these diseases are common in childhood and adolescence, measures protecting the school children are to be sought and practiced that the cardiac child may through proper care outgrow his weakness. To eliminate cardiac disease attention should be focused on the child rather than the adult.

The importance of any régime which will benefit the cardiac child is seen when statistics show that heart disease ranks higher in mortality than any other disease. Of the 148,000 school children examined in Detroit's survey over a year ago, 1,373 or less than one per cent were found to have some heart defect. This percentage was low compared to other cities.

Open Windows for Cardiacs

OPEN air schools for tuberculous and malnourished children have been of recognized benefit for a number of years. Now comes Detroit which gives its cardiac children equal benefits of fresh air, diet, and rest.

"Cold fresh air is beneficial to child cardiacs," states Dr. Harry B. Schmidt in the *Journal of the American Medical Association*, "provided they are warmly and lightly dressed with sufficient covering during rest

Open window room, Cooper school, Detroit. Cardiac children as well as the tuberculous and malnourished benefit from the fresh air.

How Will the County Board Vote?

BY THEODORE J. WERLE, EXECUTIVE SECRETARY, MICHIGAN TUBERCULOSIS ASSOCIATION, LANSING, MICHIGAN.

IN HUNDREDS of little county-seat cities throughout the United States that question, "How will the county board vote?" is agitating groups of socially minded women who are urging one type or another of county welfare reform. Just now, most of these little groups are worried over the possible fate of rural visiting nursing. "Will the board appropriate the money necessary to continue our work?" they ask one another.

During those years when Red Cross appeals brought almost an embarrassment of riches, much money was spent for rural public health nursing. For a number of years the work went on, each committee of "volunteers" in each chapter of each county in every state interpreting, according to its light, the instructions of the "Division."

Today many hundreds of these committees find Red Cross and other private funds unequal to the demands of their earlier program. In some communities it is financed by private philanthropy, and fluctuates in its effectiveness and efficiency as the funds of that private philanthropy rise or fall according to local conditions, and local interest. In other communities the nursing activity is financed jointly by the county board and a private group; and in many others the work which had gone on for some years has had to be discontinued entirely for lack of public support and the refusal of a county subsidy. One state, which at one time boasted nearly a hundred rural nurses, today is sure of only ten. Many of the others are going, or have their grips packed. Within a comparatively few months rural visiting nursing, a great public health enterprise, really vital to public welfare, has had to be abandoned in ever widening circles.

The reason for the discontinuance, in all probability but temporary, of rural nursing service is not hard to find. Elaborate programs of work were let down on rural communities by over-financed, war-born philanthropies. No effort, or only a very feeble one, was made to secure the support of the public for the work done. In fact, the very generous, almost carefree spending of money by some nursing activities committees has reacted not merely to their own undoing, but has also served to put

the stamp of extravagance on the type of work they were fostering, an unfortunate thing for rural health nursing.

For the future well being of rural public health nursing it seems wise to point out some sound methods of procedure for securing public support. How may a county be won over to the view of these excellent groups of women who are now meeting defeat? Have they been forgetting the lesson of that good axiom which all social welfare workers know?—"do not attempt to legislate too far ahead of public opinion."

Some Generalizations

The county board of supervisors is a body chosen to put into execution the will of the people of their county. Each individual member is chosen to represent the wishes of his constituents. Therefore, the county board may be expected to do what it feels to be the will of the majority of the constituents of each member. Strong personal appeals made to them by individuals who are directly promoting a project before them may interest members in a proposition but in the final vote they may be expected to act according to what they think the people back home want. It follows, therefore, that the first approach to a county board is through the influential taxpayers of each township and ward in the county. Any proposal may expect to be defeated before a county board, if the leading taxpayers are non-committal, unconvinced, or directly opposed.

The first duty of any legislative propagandist who wishes to build an honest, lasting foundation for any public welfare work is to provide a public opinion deeply favorable to his proposal. In other words, convince the taxpayer first, and be sure he is convinced. Most public health nurses are poor advertisers; and perhaps it is well that they are. Somebody should do it for them. Actual educational propaganda: literature, news-stories, lectures, meetings, resolutions, petitions, posters; all these influences should be brought to bear favorably for many months on the public mind. Such work is generally materially put forward through calling in professional social workers; workers skilled in arousing communities to consciousness of their needs.

An influential citizen from each important part of the county, where it is possible to find one already favorable to the plan, should be asked to be present at a specified meeting of the county board when the project is to be brought to the attention of the board for the first time. Important, favorably inclined members of the board should be told of the proposed visit of these people, and should be primed to ask the privilege of the floor for the spokesman of the group. This privilege will no doubt be granted without question, at a time specified.

The spokesman should outline briefly the work which has been carried on, either in the county or as reported from other places. Making clear the fact that he and other citizens of the county who have come with him feel that the general good of the county will be advanced if the proposed plan is adopted, he asks that the board consider appointing a committee from among its members to investigate the proposal for the board and report at a future meeting of the body. A member of the board, perhaps primed for the purpose, will then move the appointment of such a committee; and it is quite likely that the motion will carry.

One of the chief mistakes of the amateur welfare lobbyists who have been pushing rural nursing to the attention of county boards is haste. It is unwise to attempt to rush any legislative group to a vote on a question involving an expenditure of funds. Boards are justly suspicious of any group which does not seem to wish to give them all the time necessary for a thorough and far reaching investigation. One must be willing to "make haste slowly" with officials.

Boards of supervisors, like practically all other legislative bodies, feel that investigations conducted by members of their own group are more nearly accurate and reliable than are reports submitted by those urging a reform. The supervisors will feel a certain sense of protection against attack by unsympathetic constituents if they can point to a careful investigation by members of their own group as the basis for their action. Asking for a committee is an inoffensive way to get a plan before the group; and it gives each member an opportunity to sound his home people before he

is called to vote. Proceeding through a committee, further, is evidence of a desire to play fair. It disarms suspicion, and lets down bars of opposition. And anyway, legislative bodies like to investigate things.

With the appointing of the committee, the real work for the measure begins. Every member of the board should be visited in his home to learn his own attitude toward the proposal and to get his opinion of the attitude of his constituents. Soon it will be possible to tell what and where is the opposition to the project; and the available forces may be then directed intelligently toward breaking down the resistance.

Speakers, well informed, business-like, and to the point, should present all phases of the problem to every organized body that can be reached. The speakers should invite questions and discussion; and they should secure a favorable resolution from every group addressed. Their work should be supplemented, if necessary, with well written letters to influential individuals.

Hand bills explaining disputed or misrepresented points may be sent voters in the mails or may be sent home by school children; inexpensive posters telling salient facts, may be hung in windows and tacked up on barns and fences; and newspapers supplied with editorial and news matter. Through their columns human interest stories, as for instance, details of cases helped by a visiting nurse, should be widely used in a manner not offensive to the people involved.

In those centers where opposition seems still to persist, an actual, intensive demonstration of the work proposed for the county may be the means of winning support.

While the public campaign for support of the proposal is underway, the committee of the board of supervisors should, of course, have put at its disposal every source of available information on the work it is investigating.

Usually the professional social workers have a fund of technical information, including definite costs, which may be of much value to the committee and which may be presented in such form that it might be directly incorporated in the committee report. It sometimes happens that the committeemen will be pleased to see a tentative report drawn up for them in neat form, to use as they wish, covering the various phases of the problem under consideration.

It may be well to get some idea of the effect of the propaganda work on

the county before the board meets by arranging with the investigating committee of the board for a public hearing on the question. For such a hearing, people from all parts of the county who are favorable should be drawn in, resolutions should be unlimbered, and a speaker should be prepared to address the committee on the subject under consideration, letting it be known that he is acting spokesman for the assembled friends of the project.

A hearing like the one suggested may be considered a try-out of forces. If no opposition appears, perhaps it is a sign that the work in the county has been well done; and perhaps it means that the opponents are waiting for the meeting of the board.

As the time for the board meeting draws near, it is well to be sure of a majority vote before the board convenes. If a majority does not seem certain, it is wiser to maneuver to have the report delayed for a future meeting.

Canvass Board Before Vote

By canvassing the board just before the meeting one can be reasonably certain of how the vote will go. If the committee has been properly interested and convinced, the chairman will be anxious to see his report favorably acted on. Should he feel, and the canvass show, that the vote is not going to be favorable, he may be willing to go before the board with a request for more time.

One may wonder at this desire to avoid an open vote when defeat seems certain. Why not take the chance and try again for success later if necessary? The general feeling of experienced lobbyists may be expressed in the words of one who said: "As a general rule, a measure once defeated is a measure always defeated." This statement is not exactly true, but it demonstrates how seriously men of wide experience in legislative work regard a negative vote. It is infinitely harder to break down the evil precedent of a defeat than it is to work from zero up in a new field; and it is almost certain to be true that much more time will be lost in overcoming a defeat than will be required to win over the few hesitating members sufficient to give a favorable majority. Therefore, one should be willing to take a postponement rather than an open defeat if possible. And during the period of postponement work may be carried on to make up the votes needed to win.

The manner in which the affair is conducted before the board may in-

fluence the vote the measure will draw. Members of a board of supervisors, like most other groups of business men will appreciate any efforts made to conserve their time. Arrangements should be made in advance with the chairman of the board for a place on the calendar of the meeting, in the period allotted to discussion of the committee report. The chairman will no doubt first call upon the forces supporting the measure to open discussion.

A well organized hearing will have a "ring master," or leader who will perhaps speak first and then take command of the time allowed, by introducing other speakers, and all evidence to show his side of the case.

A good leader, in matters such as these, never overlooks the effect of the person who rises to protest. For some reason, one protest seems to carry more weight with boards than does a number of indorsements. Tax-payers in favor of a measure, usually do not trouble themselves to go before the board to say so. They must be urged to come out in support of their measure and frequently the means must be provided to get them there, if they are to be there at all. On the other hand, tax-payers opposed to a measure generally may be expected to appear to voice their disapproval. Therefore, the good leader gets favorable people to turn out for the meeting and at the proper time he introduces them, one by one, and informs the board that these people have come to give personal assurance of their whole-hearted support if the board will act favorably. The resolutions from clubs and societies in the county are introduced separately and read or indicated as being of favorable tenure, according to time allowed, and passed to the chairman of the board.

One form of opposition, which is very trying and difficult to handle, is the hidden, unexpressed, more or less personal suspicion of a certain type of board member. He sits, morose and glum, throughout the hearing. He had refused to express his convictions to workers previous to the meeting. All through the hearing he has had nothing to say. One feels he is certain to vote "no." His dark silence perhaps impresses some members of the board as suggesting a mysterious objection, better not mentioned; but, nevertheless, sufficient to require a "no." Five or six such men may drag enough following, or may dampen enthusiasm sufficiently to kill the measure.

It may not be possible to convince

such men with all the favorable evidence one might introduce but it may be possible to discredit them sufficiently to win over members who might otherwise follow their lead.

The leader's best effort should be directed toward getting the timid and morose gentlemen on their feet. To draw them out, he will do well to say in effect before he closes his talk:

Gentlemen, I believe you will agree with me when I say that we are gathered here, no one to seek his own ends; but everyone to seek the greatest good for our county. We may not all be agreed on the method for arriving at this greatest good. There may be men here, just as earnest, everyone of them, in their desire to serve the county well, as we are; men who do not feel, however, that this plan is the wise one. Those of us who are advocating this measure are anxious to do the right thing. We are not infallible; and we should be glad to get the viewpoint of everyone who sees this thing differently from us. Mr. Chairman, I wish to make it clear that no one supporting this measure will hold it against any man, if he rises to ask questions or to interpose objections. It seems to me that now is the time for us all to give every one of us the advantage of his own thought on this matter.

He may, then, very genially reach directly for his man, saying, "If I may, Mr. Chairman, I'd like to suggest that Mr. B— give us the benefit of his opinions. His thought means much to the people of the district he represents; and to us here."

The leader will perhaps, hold the floor while questions are asked, or even while unfavorable speeches are made, answering each man in a respectful, kindly tone; in that manner, and by direct appeal for any other dissenting opinions, encouraging the last hidden opponent to voice his disapproval. Usually the hidden objections are most easily answered, although their proponent may not be convinced. Such cases arise less out of an actual misunderstanding of the problem than they do out of a conservatism typical of some rural representatives. Getting them up on their feet to take part in the discussion, even if apparently unfavorable, is often the means of getting a "yes" from them in the vote.

The leader closes, saying: "Gentlemen, we lay before you what seems to be the wish of the people of this county. The matter is now left in your hands."

If all has been planned well, some chosen member of the board will be on his feet in a moment, moving the adoption of the proposal. The vote will be taken and perhaps you will have won.

Deaths in Early Infancy

THE reductions that have been made in infant mortality are due to a decrease in the number of deaths occurring after the first month. An article in the October issue of the *Statistical Bulletin* of the Metropolitan Life Insurance Company shows that little if anything has been done toward reducing the mortality that occurs during the first month of life. The article reads, in part, as follows:

The first month is by all odds the most hazardous in the entire span of human life. It is easier to survive a year at age sixty-five than for a new born infant to reach the age of one month. Each year in the United States, more than 105,000 babies die before they are a month old. This means that more than four per cent of all the two and one-half million live-born babies in the United States die in this early period. The stillbirths and the deaths of infants under one month account for the deaths of more than two hundred thousand children. These deaths are more in number than those from tuberculosis and all of the infectious diseases combined except influenza and pneumonia.

Infant mortality after the first month has been reduced one-half through such work as better feeding and care of babies. But the stillbirths and early infant deaths stay just about where they were fifteen or twenty years ago. The record of even the past five years shows no substantial improvement. In 1916, 4.3 per cent and in 1920, 4.2 per cent of the babies live-born in the United States Registration Area died before they reached the age of one month.

Yet, it is not true that nothing has been done or that the situation is without hope. The movement for the care of mothers in pregnancy, was organized not only to insure the safety of the mother, but also the survival of the baby during the first

month of life. It is interesting that, in large measure, this work has succeeded, although not to the degree hoped for. If more babies and mothers are to be saved, it will be necessary to develop a program which combines not only prenatal work but also provision for excellent confinement care. Often good prenatal work is ruined and rendered worthless by poor confinement care.

That something can be done to reduce this annual toll of deaths of very young children is evident from the facts for certain cities in the United States Birth Registration Area. In forty-seven cities of the United States during 1920, the infant mortality rates under one month of age varied from 33.6 per 1,000 births in Oakland, Calif., to 53.9 per 1,000 in Lowell, Mass., as shown in the foregoing table.

The wide range of the rates for the mortality of infants under one month of age suggests, first, that there is as yet no established minimum rate and second, that much of the mortality may be caused by so-called environmental factors which influence also the mortality of infants beyond one month of age. This latter point is suggested by the fact that in about half the cities the rate for infants under one month of age is high where there is also a high mortality for infants in the last eleven months of the first year of life. The casual agencies of much of the early infant mortality seem to be the ignorance of mothers regarding the hygiene of pregnancy and the care of babies, and the inexperience of so much of the obstetrical service available throughout the country.

Pessimism with regard to the saving of early infant life is entirely unwarranted by the facts for small groups which receive adequate obstetrical and nursing care throughout the puerperium. The appalling figures on the destruction of lives full of promise persist because, on a nationwide scale, practically nothing is being done that can be done.

INFANT MORTALITY RATES IN AMERICAN CITIES, 1920

Modern Medical Service On An Ocean Liner

A SHIP'S doctor has the most unique practice in the world.

All nationalities, all classes, and nearly all creeds seek his advice and aid. He is at one moment a physician, at the next a surgeon, and not infrequently is he called upon to act as a dentist. The ship's doctor on a modern trans-Atlantic liner may have as many as three or four thousand people who in sickness or in accident look to him for aid. He is usually the sole recourse of the passengers and crew. In order to be a good ship's doctor he must possess an extra supply of quick and accurate judgment. He must be versatile for his cases cannot be referred to specialists; the facilities of the great city hospital with its staff of physicians and surgeons are beyond his reach. At one moment he may treat a duke or a duchess and at the next an Armenian peasant. He may extract a tooth when the ocean is as calm as a mountain lake or in the midst of a terrific storm perform a delicate major operation. His life is not devoid of variety and is allotted a fair proportion of thrills.

There has been a great advance from the one room allotted the ship's doctor in the past to the modern ship's hospital. In those days the patients waited in the passage way outside the stateroom that served the doctor as both living room and office,

and any place where the doctor and patient chanced to meet was a consultation room. Now the vessels of progressive lines contain one or more surgeries, an adequate number of hospital beds, dispensary, waiting room and consultation room. Facilities are condensed for space is never wasted on the modern steamship, but they are complete, up-to-date, and well adapted to the service required.

In order to give readers of *THE NATION'S HEALTH* a conception of the equipment and services that progressive passenger lines now provide for their patrons, an interview was secured with J. C. Beaumont, chief surgeon of the S. S. Majestic of The White Star Line. A new and excellent liner throughout, the Majestic's medical services and equipment are of an equally high standard of excellence.

Dental Equipment Complete

The staff is composed of Chief Surgeon Beaumont, Assistant Surgeon Jones, two trained hospital attendants for day duty, one trained hospital attendant for night duty, and two trained hospital female nurses. One of the latter is certified in midwifery and her special services are available at any moment of the day or night for any urgent case.

The major portion of the space devoted to medical services is in the forward

ward part of the ship and though approximately under the bridge, it is more than 280 feet from the bow, an advantageous position since this is the steadiest part of the vessel. Some little distance above the water-line and on the port side is the main surgery. The walls are covered with instrument cases and lockers that provide ample storage for supplies. The operating table and all appliances are modern and of the best type and construction. A dental chair and complete dental outfit is also provided. In calm weather ample light for the application of dressings and the like is supplied from large port holes. Directly opposite the surgery, on the starboard side of the ship is the hospital. Easy and direct communication between the surgery and the hospital is provided by a passage way running across the ship from the surgery to the forward part of the hospital.

The hospital is in thirteen sections and is equipped with a total of sixty beds. Twelve of these sections containing 48 beds are devoted to general cases. The isolation section, 12 beds, for the treatment of communicable diseases affords complete isolation, i.e., in conformity with the strict English Board of Trade Regulations it is completely separated from the sections where the general cases are cared for and is provided with an uptake draught that is carried aloft and over the side of the ship. Bath room facilities are ample and linen closets commodious and well stocked. A second surgery that is practically a duplication of the one already described is located amidships aft. Directly aft of the main surgery is the surgeon's living room and office, a dispensary with an extensive and carefully selected stock of drugs, and a large and beautifully finished waiting room for the patients opening into the passageway leading forward from the passengers' quarters.

First and second class passengers are seen at any and every time by Dr. Beaumont. They come to the doctor's waiting room and are received for consultation in his office or when need arises they are visited in their staterooms. The third class passengers are attended by Dr. Jones in the large surgery aft. The crew are seen in the forward surgery by the assistant surgeon. By means of this division all clashing of patients is avoided.

The out-patient department is open

View of one of the thirteen sections of the hospital on the S. S. Majestic, the world's largest ship.

View of the main surgery on the *Majestic*, showing Dr. Beaumont operating

twice a day, in the morning at nine and in the evening at 5:30. During the travelling season the number of visits and consultation per day varies from forty to seventy.

Operation on High Seas

During the five years that Dr. Beaumont was surgeon on the *Olympic* he performed 156 operations under general anesthesia and since the *Majestic* was commissioned in May, 15 more operations have been performed. The most remarkable feature is, in view of the many newspaper stories and communications to medical journals relative to the difficulties of operations at sea, that at no time has the ship been stopped or even slowed down during any operation. Dr. Beaumont stated that the navigating officers were never told when an operation was to be performed and usually learned of it after its completion when the information became a matter of ship's news. We believe this to be a very unusual record and it surely differs from the current stories of the necessity for stopping vessels during surgical operation and pouring oil on the troubled seas.

In a later conversation with one of the officials of the line this record was mentioned and the following story was told. A little over a year ago this official was crossing on the *Olympic* on which Dr. Beaumont was surgeon at the time. A severe hurricane was encountered, so severe in fact that even the monstrous *Olympic* was in

the words of the narrator "knocked down." A heavy steel bulkhead door broke loose and fatally injured one third class passenger and crushed the foot of another. Dr. Beaumont wanted to amputate but the immigrant understood little English and could not be impressed with the seriousness of his condition. Blood poisoning set in immediately and a few days later while the hurricane was but little abated it was seen that an amputation was imperative. The

doctor, putting his hand on the leg above the knee delivered an ultimatum, "I cut, you live. No cut, you die." This time the injured man was convinced and with the ship rolling and pitching in the storm the leg was amputated with speed equal to that attained on a stationary table that is so often considered essential. Four days later the patient was taken ashore. The narrator concluded, "Probably Dr. Beaumont didn't tell you that." He didn't. He gave the impression that the difficulties under which he practiced were no difficulties at all.

Trouble Only Once

During these nineteen years, Dr. Beaumont stated that only once had any operation given him any trouble. In this case some splinters of steel were embedded in a man's eyeball. The doctor had considerable difficulty in extracting them because of the roughness of the sea and though for a time he thought it might be necessary to ask that the ship be slowed down he finally succeeded in removing the splinters from the eye without any change in the ship's course or headway and the patient had an uneventful recovery.

The *Majestic* is an extremely steady ship and cases of seasickness are at a minimum. Dr. Beaumont said that in seventeen crossings that he has made in her since she was put in service he has had but two cases that have given him even a passing moment of worry.

Dr. Beaumont acting as ship's dentist, in the forward surgery.

Digest of Sanitary and Hygienic Advance

DUE to the increasing requirements imposed by the quarantine laws of the United States and other countries, especially with reference to rodents, the Public Health Service has felt the need for further study of the subject of ship fumigation. For this reason the Surgeon General convened a board on March 1, 1922, consisting of a medical officer, a chemist, and an engineer to inquire into the subject and make recommendations. The preliminary report of these investigators (*Pub. Health Rep.* xxxvii, No. 44, p. 2744, Nov. 3, 1922), states that the two main divisions of the work are: (1), the investigation of the various gases that seem to offer advantages in ship fumigation, and experimentation regarding the production of these gases; (2) the investigation of natural ventilation and in addition the artificial means of ventilation of ships after fumigation.

In the United States, hydrocyanic acid gas and sulphur dioxide, have been largely used for ship fumigation. Each of these gases has certain advantages and disadvantages not possessed by the other. Neither is ideal. Sulphur dioxide, while fairly efficient and giving warning by its odor in time to allow the escape of any person within the quarters where it is being used, has the disadvantage of being costly, diffusing poorly, is harmful to most tissues, articles of clothing, foodstuffs, seeds, etc., and from a financial standpoint, the requisite length of time for exposure—from 5 to 12 hours—is extremely important to the ship-owners. Hydrocyanic acid gas has the advantages of being very toxic in the percentage in which the gas is used, is less costly than sulphur dioxide, requires only a short period of exposure, and does not affect foodstuffs, fabrics, clothing etc. The main objection to its use is that, being practically odorless and nonirritating, numerous fatalities have resulted. From a study of these two gases the requirement for an ideal ship's fumigant were found to be: high toxicity; easy detection, by the senses, in sub-lethal concentration; harmlessness to foods; efficient penetration; nonpersistence; reasonably low cost; no fire or explosive hazard; and ease of manipulation. It should also be non-corrosive to metals and it must at the same time be harmless to fabrics.

Special attention was given in the

investigations to the gases containing the cyanogen molecule, as it appeared in a review of the literature that a number of these gases not only possess the toxic effect of hydrocyanic acid, but were also tear gases. A mixture of cyanogen chlorid and hydrocyanic acid gas proved the most satisfactory of the various gases and combinations of gases tested. This was prepared by adding sodium cyanid and sodium chlorate to hydrochloric acid. Talc may be used with this mixture to reduce the fire and explosive hazard. A tentative formula which appears to give the most satisfactory results per 1,000 cubic feet is:

- 4 ounces powdered sodium cyanid;
- 3 ounces sodium chlorate;
- 2 ounces talc;
- 17 fluid ounces commercial hydrochloric acid, sp. gr. 1.15 to 1.20;
- 17 ounces water.

The talc and the sodium chlorate were mixed first, then the cyanid was added and mixed, and the bag containing the mixture dropped into dilute acid. The composition of the lethal mixture expressed in milligrams per liter is as follows:

Cyanogen chlorid	0.9407
Hydrocyanic acid gas.....	0.3269

This mixture fulfils the following requirements:

- (1) *Toxicity:* High toxicity with rodents, bats, roaches, bedbugs. (The amount required for lice requires further experimentation.)
- (2) *Detection properties:* Intense laceration when lethal dose used. In 1/8 lethal dose (having no harmful effect on rats after exposure of one hour) laceration was still extreme.
- (3) No effect on foods, tobacco, fabrics, leather, and no corrosive action on metals (with the possible exception of nickel).
- (4) Efficient penetration qualities.
- (5) Non persistence: Gas is not more persistent than hydrocyanic acid gas, probably less so.
- (6) Reasonably low cost per 1,000 cubic feet. Cyanogen chlorid mixture, \$0.088; hydrocyanic acid gas, \$0.081.
- (7) Fire and explosive hazard at a minimum.

Through the courtesy of the Chemical Warfare Service this work was carried on at the Edgewood Arsenal. As soon as the ventilation studies are finished, it is expected to present both the chemical and ventilation studies as a service publication. Corrections in the preliminary report are recorded in a later issue. (*Pub. Health Rep.*, vol. xxxvii, No. 47, Nov. 24, 1922, p. 2904.)

Discharge of Sanitary Sewers

In studying the discharge of sewers in Phoenix, Ariz., Cotten found (*Eng. News-Record*, lxxxix, No. 20, p. 837, Nov. 16, 1922) by the use of specially constructed floats that the actual discharge of the sewers under consideration was greater than their rated capacity as calculated from Kutter's formula. The values so derived indicated that the actual value of *n*, the coefficient of roughness, is somewhat less than 0.013 in what the author calls "an ordinarily well constructed vitrified clay sewer." Another point of interest brought out in the study was that the maximum rate of sewage discharge was practically constant throughout the year, though the total discharge varies, increasing in the summer. The maximum residential rate of discharge occurred on Sunday, about noon, and was 17 per cent greater than the maximum for any other day of the week.

Seattle, Wash., has scrapped three Meldrum destructors and now fills land at sixteen places in the city with garbage, ashes, and refuse, at a cost of thirty cents a ton. There is practically no nuisance and the made land has been approved by the city building department as suitable for light structures. (*Eng. News-Record*, lxxxix, No. 21, Nov. 23, 1922, p. 876.)

Sulpharsphenamin

A new arsenical for use in the treatment and control of syphilis which appears from laboratory findings and some preliminary clinical data to possess certain definite advantages over the arsenicals in use at the present time, differs in its chemical structure from nearsphenamin in that it has a side chain with one more atom of oxygen. Sulpharsphenamin is prepared from arsphenamine, formaldehyd, and sodium bisulphite. Voegtlin, Johnson, and Dyer conclude from the experimental findings (*Pub. Health Rep.*, xxxvii, No. 45, p. 2783, Nov. 10, 1922) that this new drug has certain definite advantages over nearsphenamin, as (1) ease of manufacture, (2) great stability of the drug in dry form and watery solutions, (3) constancy of toxic and parasitical action of different lots, and (4) suitability for hypodermic administration. It will be necessary to give this drug an

exhaustive trial as to its curative powers in human syphilis.

The Oral Route in Immunization

Nicolle and Conseil (*Ann. de l'Inst. Pasteur*, 1922, xxvi, 8) conclude that the method of Besredka is an efficacious means of immunization against Malta fever and Shiga dysentery. While the total number of experiments is not large, they hold out considerable promise of an improved method of prophylaxis against these diseases.

The Economics of Public Health

Freemantle (*Brit. Med. Jour.*, 3217, Aug. 26, 1922, p. 338 *et seq*) discusses the material loss occasioned by physical sickness and disablement and the material advantages that may be obtained, or have been obtained, from improvements in the public health and concludes that the ascertainable cost of sickness and disablement to the community in England and Wales amounts to no less than £150,000,000 (about six and a half million dollars) per annum. Judging from the estimate of £94,000,000 (\$423,000,000), Freemantle believes that the estimated loss of £150,000,000 from all forms of sickness to be grossly underestimated. The public health services of England and Wales cost many millions a year but during the course of the public health movement in the past sixty years the improvement in health has given a very large possible increase in output, which, reckoned on the basis of lives saved and the average wages of an agricultural laborer sixty years ago, works out at £62,000,000 (\$279,000,000) a year. Reckoned from the increased expectation of life, it amounts to £200,000,000 (\$900,000,000) a year, many times the amount expended on maintaining the public health services.

Experiments on the fertilizing value of activated sludge carried on by H. D. Brown show (*Eng. News-Record*, lxxxix, No. 21, p. 885, Nov. 23, 1922) that the nitrogen in activated sludge was readily available for plant food and was in assimilable form; that the sludge was very beneficial when applied immediately before planting; that it gave a rapid early growth which exceeded that of other commercial fertilizers used; and that the maturity of the plant was hastened by sludge, so that the value was

greater because it could be marketed earlier.

Re-test of Old Index of Nourishment

Bornhardt's index was designed as a test for fitness for military service, the original article being published in the *Petersburger medizinische Wochenschrift* in 1886. Guttman has recently made a study (*Arch.f.Kinderh.*, lxxii, No. 1, Sept. 9, 1922, p. 23) (*J.A.M.A.*, vol. 79, No. 21, Nov. 18, 1922, p. 1805) comparing this system with those suggested by Pignet, Pirquet, Rohrer, and Livi. Guttman has recorded the various measurement from the first to the thirtieth year of life of 10,867 individuals and applied these to the various systems under consideration. He found that from 52.5 to 78 per cent of the objective findings failed to conform to the theoretical indices with all except the Bornhardt index. The latter conformed to the facts in all but two or three cases per thousand. The formula is $G - B.L: 240$, in which G = net weight; B = chest measure; L = height (metric system). The formula is thus the weight minus the middle chest measure multiplied by the height without shoes, and divided by 240. The author states that this index is as free from errors as possible; that it can be easily applied in all countries; that it is a useful check on other methods; and that it is not an index of the constitution or potential energy, but solely an index of the state of nourishment.

Cecil and Steffen report (*Pub. Health Rep.*, xxxvii, No. 44, Nov. 3, 1922, p. 2735) that the intratracheal inoculation of monkeys with three doses of pneumococcus Type I vaccine renders them completely immune against experimental pneumococcus Type I pneumonia. The mere spraying of the throat with the vaccine was not satisfactory, probably due to the fact that the monkey, by closing off the nasopharynx, prevented the vaporized vaccine from entering the trachea. The demonstration that there exists little or no protective substance in the blood serum of the monkeys indicates that the immunity is probably cellular in character.

Compilations made by the Bureau of the Census indicate that 1921 was a remarkably healthful year. The crude death rate from all causes in the registration area was 11.6 per 1,000 population. The figure for 1920 was 13.1.

Announcement of provisional figures for the first six months of 1922 indicate higher death rates than for the corresponding six months of 1921. For the states compared the death rate for the six months was 12.6 against 12 for the first six months of 1921.

A similar comparison of the birth rates indicate a lower birth rate for the first six months of 1922, 22.7, than for the corresponding six months of 1921 when the rate was 24.8.

Relation of Colloid Silica to Infection

In the absence of Cummings, Tyler demonstrated at the meeting of the Cardiff Medical Society, November 7, exhibits showing that silica in colloidal form possessed a marked power of inhibiting the action of complement, thus preventing the lysis and destruction of bacteria by blood fluids. One series of preparations shown had been prepared by adding to serial dilutions of typhoid broth culture an equal volume of sterilized normal saline. From this mixture a measured volume had been added to an equal amount of fresh normal human blood, the preparations then having been placed in the incubator at 37 degrees Centigrade for an hour and forty minutes. At the end of that time the contents of the tubes had been transferred to the surface of trypsin agar slopes and incubated over night. Few colonies had developed on the agar showing that the bacilli had been killed by the lytic action of the blood. The next series of preparations shown had been prepared from a series of similar dilutions of typhoid broth that were mixed with equal volumes of silica colloid. The trypsin agar slopes made from these cultures were covered with colonies of typhoid bacilli showing that in spite of the lytic substances of the human blood the bacteria had been preserved from destruction during the period of one hour and forty minutes contact at blood temperature.

That this prevention of lysis by silica colloid was due to interference with the complement was shown by another series of tubes in which the complete inhibition of lysis of sensitized red blood corpuscles by the presence of silica colloid was demonstrated.

These observations may have bearing on the action of silica in leading to the establishment of bacterial diseases in the tissues, while the inhibition of cytolytic activity noted may throw light on the observation of Mavrogordato, that macrophage cells

containing ingested silica were protected from autolysis and digestion in the lymph spaces. (*Lancet*, vol. II, No. 5177, p. 1072, Nov. 18, 1922.)

Danger in the Use of Carbon Tetrachlorid

Observations by Smillie and Pessoa that dogs suffered definite fatty degeneration of the liver and kidneys following the administration of carbon tetrachlorid led them to caution against the indiscriminate use of this drug on humans. Docherty and Burgess (*Brit. Med. Jour.*, No. 3228, p. 907, Nov. 11, 1922) report similar effects on men.

With the approval of the superintendent of prisons for Ceylon and the personal consent of the prisoners, two condemned men were treated with 5 c.c. of carbon tetrachlorid and one with 8 c.c. in two doses of 5 c.c. and 3 c.c. Autopsies revealed lesions in the liver in two cases. The authors conclude that it seems inadvisable to prescribe a 5 c.c. dose with purgative, let alone without. They suggest a 3 c.c. as a safe maximum, since this has been given to a number of patients in Ceylon without discomfort though no autopsy has been performed on an individual so treated to ascertain if liver or kidneys were injured.

These findings differ from those of Leach (*J.A.M.A.*, lxxviii, No. 23, p. 1789, June 10, 1922) who gave a condemned prisoner a 10 c.c. dose and a 2 c.c. dose a week later. From the autopsy performed after the execution each reported normal spleen, liver, and kidneys.

Tuberculosis and Vital Capacity

An attempt has been made by Myers (*Am. Rev. Tb.*, vi, No. 8, p. 708, Oct., 1922) to correlate the symptoms, vital capacity reading, physical and x-ray findings in a group of 619 cases examined for tuberculosis. In 149 patients in whom physical examination revealed no evidence of diseases the average vital capacity was found to be approximately 103.0 per cent. In 100 cases suffering from chronic bronchitis the average vital capacity was slightly higher than 103.0 per cent. Twenty-nine cases with pleurisy showed an average vital capacity reduced to 92.0 per cent. All groups of cases with evidence of parenchymatous lesions showed reduction in the average vital capacity. The average vital capacity was found to decrease with the extent of disease revealed by

x-ray findings and physical signs. There was also a decrease in the average vital capacity with increase of symptoms.

Another study by the same author (*Arch. Int. Med.*, xxx, No. 5, Nov. 15, 1922) states that thirty cases in which stereoentgenograms showed no evidence of disease, the mean vital capacity was 102 per cent of normal. In 39 cases of peribronchial tuberculosis the average vital capacity was 97 per cent. When pulmonary cavities were revealed by Roentgen rays the mean vital capacity was 64 per cent. Spontaneous or artificial pneumothorax cases were found to have a mean vital capacity of 49 per cent. In the majority of cases the vital capacity was found to be reduced in proportion to the extent of involvement.

Ratner states (*Arch. Pediat.*, xxxix, 11, p. 762, November, 1922) that rabbit hair which is found in pillows, mattresses, comforters, felt hats, factory dust, toys, and clothing should be placed second to horse hair as a causative agent on the keratin group of asthmas.

Statistics on the Prevalence of Dengue

The very incomplete statistics available (*Pub. Health Rep.*, xxxvii, No. 48, p. 2941, Dec. 1, 1922) show that seven states had nearly thirty thousand reported cases of dengue fever during the summer and autumn of 1921. Texas reported the most, with Louisiana, Georgia, Florida, and Mississippi ranking in the order named.

The death rate from cancer and other malignant tumors in the registration area (exclusive of Hawaii) was in 1917, 82.0 per 100,000 population; in 1918, 80.3; in 1919, 80.5; in 1920, 83.4; and in 1921, 86.0. (*Pub. Health Rep.*, xxxvii, No. 47, p. 2899, Nov. 24, 1922.)

A series of eight essays on vital statistics by Falk (*Pub. Health Nurse*, March, April, May, June, July, Aug., 1922) present in a concise and lucid manner the sources, procedures, and results of statistical inquiries, together with cautions which the untrained statistician must observe.

Test of Commercial Vitamin Preparations

The efficacy of twenty-one different commercial vitamin preparations has been tested by Bailey, Cannon, Fisher (*Conn. Agr. Exp. Sta., Bulletin* 240,

August, 1922) by comparing the growth of young albino rats with the growth of control rats fed with an equal weight of dry brewers' yeast.

Chemical analyses of the preparations showed that "apparently many manufacturers are not entirely convinced of the efficacy of their vitamin preparations unassisted and have therefore added various medicaments of established reputation in therapeutics for good measure or to insure a reaction of some description." Such dilution offers an explanation for the observed impotency of some of the preparations. The potency of the several products examined was judged primarily from the effect on the growth curves of rats of daily doses of one hundred milligrams compared with a like quantity of brewer's yeast under like conditions. Products that proved effective with this dosage were tried with lesser amounts; those effective in fifty milligram doses were again reduced to twenty-five milligrams.

Three of the twenty-one preparations tested brought the experimental animals to their normal weight within the duration of the period of the experiment; four preparations produced growth closely approximating that secured in the controls; five produced inconsistent or indifferent growth; and the others failed conspicuously in all trials.

The *Schweizerische medizinische Wochenschrift* for October 19, 1922, states in regard to a law relating to tuberculosis now being drafted in Switzerland, that the outstanding and to a certain extent novel feature of this law is its explicit admission that if the liberty of the tuberculous individual is to be curtailed for the benefit of the public, it is incumbent on the public to compensate the individual. (*Lancet*, vol. II, No. 5177, Nov. 18, 1922.)

Pathometric Index Number

A methodological paper by Pearl (*Bull. Johns Hopkins Hosp.*, xxxiii, 381, p. 406, Nov. 22, 1922) is a preliminary account of an attempt to devise a method of obtaining a pathometric index number, which has for its purpose the obtaining of a single numerical expression of the gravity of the whole pathological picture disclosed by the lesions discovered at the autopsy. The index is derived from a formula which employs weighted scores of (1) the magnitude and gravity of the lesion; (2) the organ or organ system in which the le-

sion occurs; (3) the etiological factor involved in the production of the lesion; and (4) the age of the person.

Syphilis in Pregnancy

Realizing that syphilis is a great causative factor in premature deliveries and macerated feti, Welz and Van Nest have conducted an investigation (*J. Obst. and Gyn.*, iv, 4, Aug. 1922) through the prenatal clinic of the Detroit department of health. The study covers a total of 1,467 new prenatal cases of which 47.6 per cent were white and 52.4 per cent were colored. Of the total 13.1 per cent were diagnosed as syphilitic. Among the white patients 5.7 per cent were syphilitic and among the colored 19.3 per cent. Of the total of 193 patients having syphilis, 147 were cared for through pregnancy. About 85 per cent of the mothers having syphilis were diagnosed as latent syphilis. It was not through complaint but through routine examination that these were discovered. Since syphilis is transmitted through the placenta to the fetus after a period of about three months it is evident that early treatment is essential. It is questionable whether antisyphilitic treatment through the mother can be of any value to the fetus in utero when the vital organs of the fetus are severely involved, but it should be attempted even at the end of pregnancy in hope of securing a controlled case which can be further cared for after birth.

The injection of neosalvarsan was not found to produce miscarriages or premature deliveries. With a small initial dosage, 0.3 gm., and an increase to 0.45 gm. to 0.6 gm. in weekly injections, no harm results.

Dried Milk Powder in Infant Feeding

The scarcity and high price of milk in some portions of the country together with the abundance and waste of milk in regions lacking in adequate transportation facilities make the use of dried milk powder highly desirable. Objection to the wider use of such products has often been made on the ground that its nutritive value was inadequate. Clark and Collins (*Pub Health, Rep.* Oct 6, 1922) report a study carried on among infants in the city of Boston which indicates that dried-milk powders and their remade products are safe for infant feeding. The conclusions are based on observations and records of 241 babies under six months of age when placed on diet, and no in-

fant was included in the final tabulation unless there was a record of weighings for at least four weeks. The average gain per baby per day in Group I (fed on grade "A" milk) was 0.629 ounce; in Group II (fed on whole milk powder reconstituted in their homes) the gain was 0.880; and in Group III (fed on skimmed-milk powder and sweet butter fat emulsified in a commercial dairy) the average gain was 0.713. The authors state that while gain in weight alone may not be considered sufficient evidence on which to base final conclusions, it offers the most reliable index for mathematical demonstration.

The infants in Group II gained in weight more rapidly than did those in Group I, and their feces contained less gram positive bacilli. A study of the total number of microorganisms in the stools shows the lowest count for breastfed babies with Group II (receiving whole milk powder) second. Fresh supplies of the three types of milk were compared for total bacterial count. Whole-milk powder, when made up gave a count of 1,600 per c.c., while the Grade "A" milk was never less than 6,000 per c.c., averaged 32,000 per c.c., and in hot weather often ran as high as 200,000 per c.c.

It was assumed in this study that the preparation of dried-milk powder reduced or destroyed the antiscorbutic value. The majority of the infants were fed orange juice. Thirteen infants failed for one reason or another to get the orange juice and one in Group I and one in Group III developed symptoms of scurvy but responded promptly to treatment. In regard to the prevention of rickets the writers state that as far as can be at present determined, neither dried nor fresh milk can be considered a determining factor. The short period covered by the report made it impossible to draw any conclusion as to the effect of the diet on a number of infants included in this study that undoubtedly had previously a slight degree of rickets.

This study appears to have been very carefully conducted, is presented with great detail of statistical analysis, and indicated no nutritional or bacteriological objection to the powder and remade products that were used.

A New Method of Water Filtration

A method of purification that gives excellent color removal when used with soft, highly colored water has

been devised by H. W. Clark, Chief Chemist of the Massachusetts Department of Health, and tested at the Lawrence Experiment Station. Slow sand filters are from 25 to 30 per cent efficient in removing color from the water of the Merrimac River. Coagulation and rapid sand filtration when applied to such water tends to increase the corrosive properties. The process is of particular interest where the presence of organic matter is such as to promote undue bacterial growth.

The new process consists essentially in loading the sand of a slow sand filter with the ordinary coagulants used in mechanical filtration and operating the filter at slightly more than the usual slow sand filter rates, or about five or six million gallons per acre per day. Mr. Clark states in the *Engineering News-Record* that eleven filters have been operated to date, some of them for as long a period as five years. During such a period scraping is required not more than twice and treatment with weak caustic soda for the removal of the coloring matter held by the aluminum hydroxide is required twenty-four times. This latter treatment removes from the sand the gelatinous organic matter so necessary for the retention of bacteria and therefore reduces bacterial efficiency, but final treatment with a small amount of chlorin results in a potable water. Color removal approximates 90 per cent. The cost of mechanical filtration for the water tested was six to seven dollars per million gallons while the cost of aluminum sulphate for the new method has been about fifty-five cents per million gallons.

This method of treatment is particularly applicable to stored waters of high color, the improvement of which physically is of more moment than the reduction of bacteria.

A total of \$1,209,915 is provided for in the annual appropriation bill of the Treasury for 1924 health measures. The bill includes: \$45,000 for maintenance of a hygienic laboratory; \$488,000 for quarantine service; \$335,042 for prevention of epidemics; \$23,000 for interstate quarantine service; \$50,000 for rural sanitation; \$41,500 for regulation of the production of serums and toxins; \$227,353 for maintenance of division of venereal diseases. Appropriations were also contained in the bill to cover the expenses of medical examination by the U. S. Public health service of immigrants and aliens before they are permitted to enter the principal ports of the United States.

The Greatest Frenchman

ON DECEMBER 27, 1822, in the home of an humble tanner of Dôle, was born the man who accomplished more to lift the burden of human suffering than any other single individual in the history of the race. Some years ago a popular vote was taken by a Paris newspaper as to the greatest Frenchman of all time; and it was not Louis Pasteur who was honored, but French discrimination which was justified, when Pasteur was preferred over Napoleon by a large majority.

Four major fields of scientific activity owe their foundations to the researches of Pasteur. Industrial biology with its increasingly varied applications in the arts and industries is based upon his studies of spontaneous generation and of the fermentations of wine and beer. Modern sanitation on the one hand, and modern surgery on the other, rest upon the same sure foundation of biogenesis and upon its application in the study of the diseases of silkworms. The complex science of serology is the outgrowth of what Pasteur discovered in his investigation of chicken cholera, anthrax, and rabies.

It is reasonably certain that these same discoveries would ultimately have been made by other investigators, if they had not been made by Pasteur. The invention of the achromatic objec-

tive was certain to result in the conquest of the realm of "the infinitely little." How many years would have been lost in traveling this road, which Pasteur followed so rapidly and so surely, it is impossible to conjecture. As Pasteur said of certain biological investigators of his time, "They do not know how to experiment; it is not an easy art; it demands besides certain natural qualities, a long practice which naturalists have not generally acquired nowadays." Pasteur had those "natural qualities"—of ardor, of patience, and above all of rigorous scientific caution—and he had the sound training of the physical chemist. He spared to science decades of floundering error and he saved to the world hundreds of thousands of lives. The message which he delivered at the dedication of the Pasteur Institute November 14, 1888, embodies the secret of his power, and it is a message still as pregnant with meaning as on the day the words were spoken:

Worship the spirit of criticism. If reduced to itself, it is not an awakener of ideas or a stimulant to great things, but, without it, everything is fallible; it always has the last word. What I am now asking you, and you will ask of your pupils later on, is what is most difficult to an inventor.

It is indeed a hard task, when you believe you have found an important scientific fact and are feverishly anxious to publish it, to constrain yourself for days, weeks, years sometimes, to fight with yourself, to try and ruin your own experiments and only to proclaim your discovery after having exhausted all contrary hypotheses.

But when, after so many efforts, you have at last arrived at a certainty, your joy is one of the greatest which can be felt by a human soul.

The Progress of the Year in Public Health

THE most encouraging feature of the year 1922, in the application of fundamental scientific advance to the promotion of the public health, has been the development of Schick testing and toxin-antitoxin immunization against diphtheria¹. In New York and in many other cities the Schick testing of school children has been carried out on so extensive a scale as to warrant the belief that diphtheria among children of school age will shortly be in a fair way of being controlled. Meanwhile, however, there has been a growing recognition of the fact that the war against diphtheria, if it is to be most effective, must begin before the school period, and Dr. Park's success in preparing a dilute toxin-antitoxin mixture of full protective potency, but free from any tendency to produce unfavorable reactions, clears the ways for a broader campaign of general immunization of infants at the end of the first year of life.

In the field of venereal disease control the use of the Kahn precipitation test for the diagnosis of syphilis² appears to constitute an advance in laboratory technic which is of substantial importance; while the reports of the U. S. Hygienic Laboratories³ on the use of sulpharsphenamin suggest that this drug is likely to prove of definite value in the treatment clinic.

On the more theoretical side of bacteriology the most interesting new work has perhaps been that which deals with the Twort-d'Herelle phenomenon. An English translation of D'Herelle's book has just appeared⁴ and recent American work⁵ fully confirms the reality of the bacteriophage phenomena, whether the explanation is to be sought in the assumption of a living ultramicroscopic virus or of a process of self-propagating autolysis.

Studies on the etiology of rickets from the laboratories of Hess⁶ and of Park⁷ constitute a fas-

cinating chapter in the philosophy of disease. They illustrate better than almost any other researches one could name the complexity of pathological processes by demonstrating that a disease intimately related to a lack of salt balance can be cured by two such apparently diverse agents as cod liver oil and sunlight; and they give us for the first time a definite experimental basis for the age-long therapeutic cult of Apollo.

In the general field of maternity and infant hygiene there is a growing tendency to emphasize the importance of prenatal and obstetrical service and the practical work initiated all over the United States, supported or inspired by the Shepard-Towner Act⁸, promises to yield far reaching results. The importance of a safe and cheap milk supply in promoting the success of our child hygiene program is a fundamental one, and recent studies on the value of dried milk for infant feeding⁹ indicate that the development of the use of this product is likely to furnish the solution of one of the most difficult problems in practical nutrition.

The brilliant researches of Krause continue to throw a flood of light upon the etiology of tuberculosis, a realm in which light is still so much needed after forty years of laboratory study. His latest contribution¹⁰ gives us a satisfying anatomical basis for the different reaction of the rabbit and the guinea pig to tuberculous infection and suggests a possible explanation of the differing age incidence of various forms of tuberculosis in the human subject.

The posthumous publication of the late Dr. E. E. Southard's stimulating book on the Kingdom of Evils¹¹ must certainly be classed as an outstanding event of the year in the domain of Mental Hygiene, whether or not the majority of psychiatric social workers are prepared to accept the suggested classification of the problems with which it deals.

One of the most notable tendencies of the present time is the awakening of health authorities and of the public to the serious importance of street accidents as a factor in the death rate¹². The dramatic success attained in Baltimore, New York, Washington, and other cities in controlling such accidents through "Safety Week" campaigns indicates that there are exceedingly promising opportunities for the reduction of mortality along this line.

The forces which make for health progress in the United States have been greatly strengthened

by the consolidation of the Child Health Organization with the American Child Hygiene Association and by the reorganization of the American Public Health Association along definitely professional lines¹². The presentation before the annual meeting of the American Public Health Association at Cleveland by the Committee on Municipal Health Department Practice of a plan for an ideal health department for a city of 100,000 population¹⁴ will, it is hoped, prove of substantial aid in the development and standardization of municipal health department procedure throughout the country.

Another document which deserves mention in any review of the health field is the report of a Committee on Nursing Education¹⁵, appointed by the Rockefeller Foundation to study "the proper training of public health nurses," a scope later inevitably broadened to include general nursing education as well. This report, which emphasizes the essential importance of better educational facilities for nursing education under educational management and supported by educational endowments, is stimulating developments in half a dozen university centers which promise before the lapse of another year to yield substantial fruit.

The wider question of the training of public health workers of all types was discussed at an important conference called under the auspices of the U. S. Public Health Service in March¹⁶; and this conference led to the appointment of a committee which will give continuous consideration to the problems involved in the future.

Altogether, the year has been one of substantial progress, both in the theory and in the practice of the public health,—a year which we may regard with satisfaction and from which we may take courage to go forward.

The Health Organization of the League of Nations

THE preceding summary of certain of the outstanding events of 1922 in the field of public health deals wholly with happenings in the United States. America, as we are gradually coming to realize, is after all a part of the world and the development of a strong and effective international health organization under the League of Nations is of immediate moment to us all. The meeting of the Health Committee of the League in August marked the completion of approximately the first year of its existence and was signalized

by achievements for which those who fought for the creation of the Committee in those trying days of 1921 did not dare to hope. The epidemic commission of the League has been steadily at work in Poland and plans for extending its activities northward into Latvia and eastward into the western marches of Russia and the Ukraine have been approved. Special commissions of sanitary inquiry have been sent to the Near East, to the Far East, and to equatorial Africa, in connection with the preparation of new International Sanitary Conventions and in cooperation with the Mandates Commission. It is particularly gratifying to note that America is cooperating, unofficially at least, through an arrangement with the International Health Board of the Rockefeller Foundation, by which the latter undertakes to finance two special branches of the Health Commission's work—namely, epidemiological intelligence and investigations, and the interchange of sanitary staff—to the extent, respectively, of thirty thousand dollars a year for five years and sixty thousand dollars a year for three years.

The first essay in interchange of sanitary staff began in October, in the form of a two week's course at Brussels for foreign public health officers, followed by two months of first-hand observation of the actual working in practice of various public health systems. The twenty odd officials taking this course are drawn from the health services of Belgium (2), Bulgaria (1), Czechoslovakia (2), Italy (5), Poland (5), Soviet Russia and Ukraine (5), Serb-Croat-Slovene State (2). It seems certain that this first experiment in cultivating the international spirit and giving international experience in public health service will reveal many and fruitful possibilities.

Progressive Conquest of Mosquito-Borne Diseases

THE last annual report of the Rockefeller Foundation brings inspiring news of the progress of the campaign against malaria and reminds us that the men who gave their lives in the war of the laboratory against yellow fever have not died in vain.

Under the head of malaria control new demonstrations were undertaken during the year 1921 in twenty-six localities in nine southern states and work previously inaugurated was continued in thirty-five places in ten states. Substantial reductions in the prevalence of the disease were effected at an average cost per capita of approximately one dollar. Reductions that had been secured during the previous year were maintained at an average per capita cost of twenty-five cents.

16. *The Future of Public Health in the United States and the Education of Sanitarians*. Public Health Bulletin No. 124, U. S. P. H. S. November, 1922.

The results of the campaign against yellow fever is even more encouraging and warrant the hope that Gorgas' program of radical extermination may yet be carried into full execution. In 1916, when this program was formulated, men who might have been better employed in presenting a united front to their common enemies, were fighting among themselves, but during the delay caused by the war among men one notable victory was recorded in the history of the war of man against yellow fever. Noguchi, of the Rockefeller Institute for Medical Research, visited Ecuador, Peru, and Yucatan and isolated *Leptospira icteroides* which is believed to be the causative agent of yellow fever. In 1918-1920 he prepared vaccine and serum for the prevention and treatment of the disease. From 1918 to 1920 yellow fever commissions and intensive preventive campaigns were organized in Central America, Columbia, Ecuador, Peru, and Venezuela. By means of an intensive campaign Connor eliminated the malady from Guayaquil, the chief endemic center. In 1920 a commission was sent to the west coast of Africa and late in the same year the Mexican Government organized a yellow fever commission and invited the cooperation of the International Health Board.

During 1921 Honduras, Nicaragua, Ecuador, and Costa Rica were free from the disease. Guatemala reported no case after February 2; Salvador's last case was recorded on February 15; Peru was free from the fever by July 16; and by November British Honduras was added to the list. The Brazilian government dealt with cases occurring in the northern part of the country.

Tests with Noguchi's vaccine indicate that it affords marked protection against yellow fever. Twenty-five of a group of fifty non-immune Peruvian soldiers who were being sent into an infected district were vaccinated against yellow fever. None of this group contracted the disease, while twenty cases did occur among the twenty-five unvaccinated. The value of the serum is also indicated by the results obtained in treating twelve yellow fever patients in Belize, Honduras. These patients were treated with serum on or before the third day of the attack and eleven recovered.

The war is drawing to a close and yellow fever is facing final defeat.

On Sale "As Is"

NOT knowing how long the world war would last and in order to insure themselves an adequate amount of surgical and medical supplies, our army and navy, during the eighteen months that we participated in the war, pur-

chased vast quantities of these supplies. Such was the urgency of the times that they purchased them not only from long established manufacturers but in not a few instances from manufacturers of little or no experience, and under specifications designed to meet the exigencies of the moment.

When the armistice was signed they found that there was a great surplus on hand. In due time steps were taken to dispose of this surplus. A division of sales was organized in both departments. It was the intention at first to offer these products to municipal, county, and state hospitals but these sources of outlet, it was soon discovered, were too limited. Printed lists, with definite prices, were then sent to all the hospitals in the country. Later other lists were sent out on which bids were asked. More recently the supply branch of the office of the surgeon general of the army upon approval by the director of sales has been holding auction sales of surplus medical and surgical supplies, purchased or contracted for during the war.

Each auction sale catalog stipulated that "all property listed in this catalog at said auction will be sold 'as is' and 'where is', without warranty or guaranty as to quality, character, condition, size, weight or kind, or that the same is in condition, or fit to be used for the purpose for which it was originally intended."

This undoubtedly means that while some of the products thus thrust upon the market are satisfactory, others are of questionable quality and fall short of present standards. Manufactured four or five years ago, and subjected to various climatic conditions while stored in different warehouses, or in transit to Europe and back, many of these supplies have undoubtedly deteriorated. Surgical sutures may have lost their tensile strength and their sterility; chloroform may have decomposed; chemical compounds manufactured into tablets and alcoholic extracts of vegetable drugs may have disintegrated; liquid preparations may have fermented or precipitated.

Against the war department's sales of surplus surgical and medical supplies that conform to adopted standards we do not complain, but on behalf of the hospitals of this country we most emphatically protest against the practice of selling medical and surgical supplies "as is." The practice undeniably jeopardizes health, not to say life.

The bureau of chemistry of the United States department of agriculture is vested by law with the function of administering the provisions of the pure food and drug act, and no drugs should be placed on the market by the war department, or by any other department of the federal gov-

ernment, until they have been tested, and have received the approval of this bureau.

At the very time the government is selling its citizens and non-governmental hospitals medical and surgical supplies "as is," it is buying the same kind of supplies, freshly and perfectly made, for use in its own hospitals.

Operating Factors in Industrial Hygiene

NO amount of care and money spent on the installation of a model factory, from the standpoint of safety and sanitation will yield results without continuous and intelligent expert operation. The essential factor in accident prevention is the work of the safety engineer in analyzing each accident case as it comes up and devising means for preventing its repetition. The essential factor on promoting physical health and efficiency is the work of the industrial physician and the industrial nurse in constantly studying processes, working conditions, and personnel, and their mutual reaction as revealed in sickness records and in productive efficiency.

It is precisely at this point that the machinery of industrial hygiene most commonly breaks down. A physician who comes into the plant for a few hours a day to render first-aid service or even to make routine physical examinations exactly as he might do in his own office, cannot possibly furnish the type of leadership which is essential to success. The time has gone by when any physician or any nurse could be considered good enough for industrial health service. The physician who is needed is an "industrial physician," a man or a woman who has specialized in industrial problems and who has the opportunity and the desire to study the particular problems of the individual plant so thoroughly as to bring about an adjustment between the work and the worker which will yield a maximum of results. The nurse if she is to be effective should be an "industrial nurse" with real vision of the field of public health and of its educational possibilities. At the present moment there is a widespread impression that industrial medical service has been "oversold," but the trouble lies in many cases with the type of service which has been sold and not with the essential value of health supervision. When we find that the studies of the United States Public Health Service as recently reported by Dr. L. R. Thompson indicate a 700 per cent variation in sickness rates in different plants, it seems fairly obvious that it is good economy to provide efficient machinery for controlling the factors that make for sickness. The primary element in such a pro-

gram is the employment of some one individual whose duty it is to make a continuous study of factors which affect physical health and efficiency in the particular plant in question. In certain instances it is possible to obtain expert service of this type from a physician in general practice; but it will usually be difficult to secure such leadership except from a physician whose life is devoted primarily to the study of industrial health. The plant of 500-1000 employees can well afford to employ a full-time physician of this type and the small industry can usually work out a cooperative plan for employing a specialist in industrial hygiene who shall serve two or more adjacent plants. If an industry has the vision to employ such a physician all the other details in the plant can be worked out by him. If it does not employ such a leader and coordinator but relies on casual medical assistance and inefficient nursing service, no perfection in plant construction will ever yield worth-while results.

Wider Significance of the Health Demonstration Plan

DURING the past year two notable health demonstrations have been projected—that of the Commonwealth Fund which through the Child Hygiene Association will finance a five year demonstration in three middle-western cities with a \$230,000 annual appropriation, and that of the Milbank Fund which will spend \$400,000 yearly in a similar program in a rural county, a section of a second class city, and a section of a first class city of New York state.

These munificent benefactions promise much for the cause of public health, but they are also full of significance in relation to the wider problems of American democracy. The greatest danger to the success of our democratic institutions lies perhaps not in corruption but in mediocrity,—in the inertia and the lack of vision which tend to characterize the conduct of public affairs in a nation where it is assumed that any man is good enough for public office if he be diligent enough in seeking it. The conduct of privately financed cooperative demonstration in government (for public health is a part of government), such as the International Health Board has carried on with success and such as are projected in these newer demonstrations, will tend not only to improve community health but also to convince the public that the whole art of government is of more importance than has been realized; that this art demands the leadership of experts; and that the following of such leadership will bring valuable returns in increased health and prosperity.

HEALTH IN INDUSTRY

*Problems Concerning Factory Sanitation,
Industrial Medicine, and the Health and
Efficiency of the Industrial Worker*

Claim Costs Reduced By Health Supervision*

By ROBERT S. QUINBY, M.D., SERVICE MANAGER, HOOD RUBBER COMPANY, WATERTOWN, MASS.

THIS paper presumes to deal with the methods of creation and maintenance of industrial medical service, the reduction of sickness and accident disability, and with the economic justification through savings in settlement of accident, sickness, or death claims. The greatest single appeal for health supervision is through a demonstrable financial saving of such service in connection with various forms of personal insurance as they appear in industry. The sound logic of improving health standards and the humanitarian element both contribute, but "money talks," and if it can be demonstrated that a plan of industrial health supervision will save money you have a customer.

One has little interest in or patience with many attempts to show in units of dollars and cents the accomplishments of industrial medical service. The motive is to be commended, but so many of the premises are unsound and so many variables enter in that one has little confidence in the conclusions. For instance, when it is said that so many man-hours at a given rate are lost on account of sickness or accident, it may, even under certain conditions, be an asset to be rid of the given individual, or in the case of another may mean an expense of one hundred times the man-hour-dollars involved. It is not to be inferred that I do not believe in the savings to be accomplished through the reducing of disabilities on account of accident or sickness by medical supervision, or that I do not think it desirable to study in every possible

way to measure and justify these savings, but I do plead for greater accuracy in conclusions, so that the sound foundations of industrial medicine may not be shaken when erroneous assumptions of this nature are discredited.

The methods and machinery by which a system of health supervision may be built up and conducted so that the greatest influence may be exercised in the reduction of costs in benefits, insurance or compensation, as applied to disabled workers in industry are (1) Physical examinations of applicants and periodical re-examination of those already employed. (2) Dispensary treatment of sicknesses, accidents, and in many cases care of dental, ocular, and other conditions. (3) Supervision of factory sanitation and the elimination of accident and disease hazards. (4) Absentee investigation, home nursing and medical supervision in such cases as it may seem advisable. (5) Education in health, personal hygiene, and safety. (6) Facilities for the settlement of all claims involved in any compensation or benefits for sickness, accident or death. . . .

Two years ago the Hood Rubber Company created a mutual liability insurance company for the purpose of carrying our own liability in industrial accidents. We have, since the creation of this company, entirely controlled and administered all matters pertaining to industrial accident claims, of course in compliance with state insurance regulations and compensation laws.

At the time our dispensary was established we employed approximately

three thousand workers, and this number gradually increased to an average of about 7,500 during the last three years. Throughout this period about one-third of those employed have been females and two-thirds males. There has been a representative age, nationality, occupational, and residential distribution, so that it need not be inferred that anything mentioned in this paper applies to any selected or unusual group of industrial workers.

From year to year additions were made to the health supervision program. In 1914 a dental dispensary was established as an adjunct to the medical service, probably the first in a factory in this country; later x-ray equipment was added, and in 1919 an ocular clinic was established. In 1917 physical examination of applicants for work and of those already employed was instituted, and in 1918 home visits of absentees by nurses, later supplemented by the services of a physician when desirable in sickness or accident, was inaugurated. These various activities are mentioned in order to bring out the gradual development, over a long period of time, of different cooperating branches of the medical supervision and claim settlement work, all directed toward the early detection, prevention, and reduction of disability due to disease and accident, and to show the background of the development of machinery for the settlement of all claims arising out of such disabilities.

On January 1, 1919, our benefit plan became effective. This provides for the payment of benefits in cases of sickness, non-industrial accident

*Read before the eleventh annual meeting of the National Safety Congress, Detroit, Mich., August 28, 1922.

and death, varying with length of employment from three months to five years and over, ranging from eight dollars to twelve dollars weekly, and covering a period of from seven to fifty-two weeks. Death benefits, again depending on length of employment, range from two hundred dollars to one thousand dollars at the end of five years of employment. The company bears all expenses of this plan and entirely controls and administers it. Here, again, is an example of our policy of dealing directly with our own employees in matters of personal industrial insurance. Department heads are given a considerable responsibility in connection with the investigation and approval of sickness and non-industrial accident claims. Their investigations, of course, are supplemented and in most cases initiated by visiting nurses and the medical department, but we wish to link up the department heads and foreman in the general administration of all such claim settlements.

Cases of sickness and accident, if not seen in one of the dispensaries before leaving work—and this is rare—are at the very latest discovered on the second day of absence by the nurse's home visit. The condition is determined as well as the probable disability and the case is revisited as frequently as may be indicated by given conditions. If an industrial accident, proper information of a medical nature is furnished to the foreman so as to enable him to make out the necessary accident reports. If from non-industrial accident or sickness, information is likewise forwarded to the department head in order to enable him to investigate and approve payments, so that claim settlements may be made promptly. Any new development in these cases is brought to the attention of the department head by the benefit or insurance office or, if discovered by the department head, to the attention of those in charge of claim settlements. We are always mindful of the confidences which should exist between physician and patient and do not betray these to department heads without good reason, so our workers are generally frank and free in their statements, feeling from experience that their rights and confidences will be regarded and that they will be accorded equitable treatment.

Payments both under compensation and benefit plan are made promptly and with the knowledge of department heads. In cases of question, such as will sometimes arise, we always suggest a consultant or offer to refer

the case to the decision of the accident board or to an impartial examiner. In the long run it is good policy to be as liberal as possible in such matters, for eventually you are able to build up a credit for fair dealing which will do much to help the general industrial relationship and to discourage malingering. If you are able to create such a reputation it is rare for workers to try to impose to any great extent, and in such cases as they do there is always possible speedy and effective redress.

For reasons quite apparent, I do not wish to go into detailed figures as to results, more particularly as referring to finances. In the first place, it is nearly impossible to compare such figures accurately with other experiences; conditions in two factories are rarely comparable—it is even more true in companies under different state laws as regards compensation or insurance. Then, too, it would not be feasible in many companies to attempt to carry out such work as we have found to be to our advantage. Detailed comparisons of our experience with other insurance costs are hardly fair to insurance companies, because they have many overheads that we are able to eliminate and thereby make a saving and also bad risks which must be offset by good risks at the expense of the latter, so I am simply going to give a few figures showing our disability experience and some general statements as to the economics resulting in our case, and if anyone wishes detail it will be furnished, but privately.

Because of the lack of dependable statistics it is impossible to compare our experience of recent years with that of more than five years ago. This is unfortunate, but it is found to be the situation in most plants, so the best we can do is to give our experience during such time as we have actually recorded. From all available evidence, experience would be much more favorable if we were able to go back of this period; then, too, the influenza epidemic had a very serious effect on disability records, both during its active stage and also as a result of the disabling complications which followed.

Considering first our industrial-accident disability reduction, records show that the average disability per employee per year was as follows: In 1917, 0.85 days; 1918, 0.61; 1919, 0.42; 1920, 0.39; 1921, 0.32.

Similarly, the percentage of employees who are reported disabled by industrial accidents yearly is as follows: In 1917, 0.24 per cent; 1918,

0.20; 1919, 0.14; 1920, 0.11; 1921, 0.10.

In other words, we have reduced by more than one-half the number of disabling industrial accidents and the disability time resulting therefrom during the last five years. Our experience indicates that our workers last year averaged to lose only about 5 per cent as much time on account of industrial accidents as industrial employees in the state at large. This very low rate is accounted for by our freedom from death cases plus lessened number of accidents and shortened disability per accident.

Our sickness and non-industrial accident records cover a period of three and one-half years and indicate that during that period our workers have averaged to lose 5.2 days on account of sickness and non-industrial accident. Our average total lost time from all reasons, including personal, has averaged during this time to be 5.3 per cent, while last year we were able to reduce this to 4.3 per cent, the lowest in our experience. Considering that about one-third of our workers are women and that except for accidents their rate of lost time is double that of men, we believe that these figures represent very nearly a minimum.

As to financial savings, all absence investigations, in spite of the fact that about two-thirds of the calls are on account of absences due to other than sickness or accident, are charged to the benefit plan. Including all this overhead, plus actual benefits, we were able to conduct this work for approximately one-half the cost of re-insuring this plan in a commercial company.

Our accident liability insurance company writes its compensation business at the same rates charged by other insurance companies. After having paid losses, overhead expenses, taxes, etc., and placing in reserve sufficient funds to liquidate all outstanding liabilities, we have, at the end of two years' experience, 78 per cent of earned income unexpended. This is the net percentage of profit on our total business.

Our experience satisfies us that properly conducted health supervision, cooperating with adequate machinery for reduction of lost time and for the elimination of accident and health hazards and with those in charge of the settlement of claims, economically justifies itself. Beyond this it gives us the advantage of relationships with our workers which are not measurable in dollars but which perhaps contribute more than we realize to the prosperity of the enterprise.

Laurentide Health Service, Grand'Mere, Quebec

IN THE city of Grand'Mere, Quebec, there exists a unique and significant relationship between an industrial health service and the community. The Laurentide Company, Limited, is a concern engaged in the pulp and paper industry. It owns a plant that has a daily capacity of 360 tons of groundwood pulp, 150 tons of sulphite pulp, 50 tons of cardboard, and 350 tons of newsprint. The mill and general offices, employing approximately 1,300 persons, are located in Grand'Mere which has a population of only 7,500. The city, having no hospital of its own, the Laurentide Company, Limited, was forced to operate an industrial hospital for the benefit of its employees and through the generosity and cooperation of the company the city has not only been stimulated and aided in the development of its own health service, but has been given an opportunity to share in the benefits of the complete industrial medical and nursing service of the company. Under ordinary circumstances a policy under which an industrial concern assumes responsibility for the general health of the community in which it is located may be of doubtful value. In this case, however, the small community provided very inadequate medical services on which the company could depend, and there is little question of the fact that the community is today much better off than it would be if the industry which employs a large proportion of its inhabitants were not in position to give not only employment for the citizens but adequate medical aid.

Organizing Health Board

A water supply system installed for the municipality by the company, modern residences constructed for employees, a golf course, tennis court, athletic field, assembly hall and club, library, night school, band, orchestra, and plant paper are some of the activities included in the recreational and educational program. A pension plan administered by a special committee, an inn, cafeteria, and dairy are other features instituted by the company in order that the working man in the small community can have some of the advantages that would be available in a larger city.

With the financial cooperation of the Laurentide Health Service, the municipality of Grand'Mere is undertaking the organization of a board of

health with a full time health officer and laboratory facilities for diagnostic and therapeutic purposes. Health problems concerned with general sanitation, housing, communicable diseases, food inspection, child welfare, and school life will be dealt with. The Rockefeller Foundation is cooperating in this work to the extent of providing a fellowship for the medical officer of health. A number of eminent physicians connected with McGill University and the Royal Victoria Hospital have consented to act as consultants to the Laurentide Health Service, thus making available expert advice and assistance in medicine, surgery, ophthalmology, and roentgenology. A prominent Montreal dentist is consultant to the oral hygiene clinic.

Careful consideration of the interests of the Grand'Mere physicians is the basis upon which cooperation with the municipality has been established. The company physician is a collaborator not a competitor. His services, as far as sick employees are concerned, are limited to consultations with the patient's family physician. Only under exceptional circumstances as in serious accident cases is the company physician permitted to render actual medical care. His duties relate primarily to the problems of preventive medicine and the medical aspects of group insurance. Experience has amply demonstrated that health activities of the sort embodied

in the program of the Laurentide Company ultimately increase the income and advance the interests of the general practitioners who reside in the communities where such work is carried on.

Local Doctors Use Hospital

Facilities of the Laurentide Hospital are extended to local physicians for their private patients and the charges of the x-ray department have been reduced to less than the cost of materials and maintenance so that its usefulness in diagnosis may be increased.

Though receiving the private patients of local doctors the hospital is primarily for the members of the Laurentide organization. It is a modern hospital in every respect and only graduate nurses are employed. The admission of company cases is through the first-aid office or the superintendent of the nursing service. As a rule, the hospital charges for injured employees, as well as surgeons fees, are paid by the company. Ward accommodations for medical or surgical patients who are company employees or residents of Grand'Mere is \$1.50 per day; for others \$2.00. The charges for semi-private and private rooms are from \$3.00 to \$5.00 per day. Maternity patients are received in the ward for \$2.00 per day. The operating room fee is \$5.00 for major and \$2.50 for minor surgery. Charges for ambulance service depend upon the

First-Aid Office of the Laurentide Health Service

Operating room of the industrial hospital of the Laurentide Company Limited. This hospital is the only one in the municipality and is open to all residents of Grand'Mere.

distance and the number of assistants required. Special drugs, special dressings, special medical supplies and appliances are charged at cost. Arrangements for a special nurse, at cost, may be made through the superintendent of nursing service. A relief committee has been organized to assist needy patients.

In addition to requiring that all employees of the nursing service must be graduates of training schools of recognized standing, preference is given to those that have had public health training. A physical examination by the company physician is a necessary preliminary to appointment. The entire staff is on a straight salary basis and all nurses pay for their board, room, and laundry and provide their own uniforms. Prior to appointment to the regular staff, three months duty as a temporary staff nurse is required. Those members of the staff engaged in municipal health work receive appointments under the Grand'Mere board of health.

The district nursing includes general care of the patient, bed making, care of the sick room, and instruction of the family. Continuous nursing is not provided but night calls in cases of emergency (usually for maternity patients) are made whenever requested by the attending physician. Patients with communicable diseases are visited in the ordinary day's work but such visits are last on the list.

All members of the Laurentide Mutual Benefit Association and other company employees receive nursing visits free of charge. Holders of in-

dustrial insurance policies receive visits at the expense of the insurance company.

Fees for nurses' home visits at time of confinement is from \$3.00 to \$5.00; regular visits to adults \$.75; regular visits to children \$.25.

In addition to the district nursing and the regular nursing service in the hospital, service is provided at a child hygiene clinic and the Laurentide Company's school. Five members of the nursing service are engaged in district and child welfare work. Between 1,200 and 1,500 visits to

homes are made by them every month.

Insurance features of the health service program are based on the principle of giving free life insurance to those who are sufficiently interested in their own welfare to be willing to pay for their health insurance. Health insurance is carried by a mutual benefit association backed by the company. The salary provisions of the company for staff members in case of illness are such that they are given only one-half the cost of their life insurance. No member of the Laurentide organization, except those on the salaried staff, pays one cent for life insurance; it is a gift from the company. Ninety per cent of the entire personnel belongs to the mutual benefit association which provides health insurance.

An active program of education in health and personal hygiene is carried on among both children and adults, a central safety committee directs the accident prevention work, all applicants for employment are given a physical examination and are aided in getting their defects remedied.

The medical service cooperates with the local medical officer of health in connection with problems relating to the sanitation of the community and with the operating manager of the mill from the standpoint of sanitary matters concerning the plant and its immediate surroundings.

Extension of some of the features of the health service program to the operations and personnel of the woods department of the company are under consideration. This winter the number of men in the company and job-

X-ray department of the Laurentide Health Service Hospital.

ber's camps is approximately 2,000. Owing to the large number of logs in the streams the woods department is now employing less than the usual number. Normally the employees of

this department number about four thousand.

Dr. Bernard L. Wyatt, director of the service, states that expenditures for the past year exceeded \$85,000

and that returns to the company in values that can be estimated in dollars and cents as well as more intangible results are more than sufficient to justify this expenditure.

American Association for Labor Legislation

ENACTMENT by the states of laws to provide old age pensions and unemployment compensation, and to strengthen the practical administration of workmen's compensation laws was urged in addresses on workmen's insurance before the sixteenth annual meeting of the American Association for Labor Legislation held in Chicago, December 28 and 29, by Frank E. Hering, chairman of the old age pension commission of the Fraternal Order of Eagles, the Rev. H. C. Hengell, president of the Wisconsin Association for the Prevention of Unemployment, and R. M. Little, former chairman of the U. S. Employees' Compensation Commission.

In general, persons entitled to pensions from the state fund must have been for five years citizens of the United States and for ten years residents of the state in which they apply, and have not been convicted of crime or vagabondage, and who can satisfy the proper state and county boards that their income from all sources is less than \$300 a year, according to Mr. Hering.

"The number of unemployed beyond a certain age is constantly increasing," he said. "Of men over 65, the unemployed were 26 per cent in 1890 and 32 per cent in 1900. When a machine wears out it is thrown into the scrap heap, and another, in our present industrial system, is taken in its place. Quite similar is the situation of the man who tends the machine. When his hearing, eyesight, or skill of hand begins to fail, his efficiency is lessened and business economy demands that he also be scrapped. Half of the workmen over 65 years are scrapped."

The United States alone in the civilized world, Mr. Hering asserted, has made no provision for old age dependency, but public sentiment back of the proposed old age pension laws has brought about an official investigation of the whole subject of poverty in old age in such states as Illinois, Wisconsin, Pennsylvania, Ohio, Massachusetts, California, New Jersey, and Connecticut.

"The vast army of unprovided for, worn-out veterans of toil," he concluded, "should not be stigmatized as

paupers. They should be taken from the scrap heap by the state and placed on an old age pension roll.

Mr. Little said that more effective administration is a present need in meeting the practical problems of workmen's compensation, and that there are serious doubts as to the advisability of allowing private insurance companies to carry industrial accident insurance.

"We must have a public administration that is competent, stable, and continuous," he said. "Unfortunately our state legislatures have not conceived of accident compensation administration as being on a par with the judicial and fiscal divisions of the government. Salaries are too low. Men of more ability are needed who can remain longer on the job. Medical service is unsatisfactory. There is need of better leadership. Safety work and rehabilitation should be coordinated with payment of compensation."

That the twelve-hour shift in industry, notably in steel, is destructive of health as well as of citizenship; that fatal mine accidents are increasing and call for more effective preventive measures; that compulsory arbitration is a menace to industrial peace, and that the government must aid with facts in forming a sound public opinion to combat the conditions that lead to strikes, were declarations made by other speakers.

Industrial waste and the general welfare was the subject of the discussion. The principal addresses were given by Charles R. Walker of the Atlantic Monthly, author of "Steel"; William W. Adams of the U. S. Bureau of Mines; Benjamin Selekan of the Russell Sage Foundation; John A. Fitch of the New School for Social Research, and Benjamin Squires, impartial chairman in the garment industry, Chicago.

"The 12-hour day, as I observed it," says Mr. Walker, "tended either to destroy, or to make unreasonably difficult, that normal recreation and participation in the doings of the family group, the church, or the community, which we ordinarily suppose is reasonable and part of the American inheritance."

"Another kind of inefficiency that

flowed quite naturally from excessive hours was absenteeism and a high turnover of labor," he declared. "Men kept at the job as long as they could stick it out and then relaxed into a two or three weeks' drunk. Or they quit the company and moved to another mill for the sake of change and a break in the drudgery."

"On the Monday following the exhausting 24-hour turn, Mr. Walker said 'men made mistakes; there were arguments, bad temper, and fights, and a much higher frequency of collision with the foreman. Efficiency, quality, discipline dropped.'"

Mr. Fitch condemned compulsory arbitration and declared that the public should fix the level upon which industrial disputes are conducted.

"What the public may do in the way of intervention," he said, "is the establishment of a legal minimum and the development of ethical standards. Compulsory arbitration will naturally frustrate the movement for industrial peace."

Public interest directed toward the causes of industrial disturbance is more to be desired than public hysteria manifested during such disturbances, Mr. Squires asserted.

"Unfortunately, public interest in industrial disturbances is most keen when the public is inconvenienced," he said. "Much of the legislation designed to put an end to direct action by employers or workers has been written during or immediately following prolonged industrial warfare which jeopardized public safety or comfort. The most effective of such legislation has laid major emphasis upon investigation and publicity. However, public investigation is not undertaken until the acute stage of strike or lock-out is reached or is imminent. What is needed is greater public interest in establishing and maintaining conditions that make for industrial peace without waiting until disturbance threatens or occurs."

Discovery of a serum to combat Rocky Mountain spotted fever, an acute infectious disease of high mortality, has been announced by Dr. Hideyo Noguchi of the Rockefeller Institute for Medical Research.

The Nurse in Industry

By ELIZABETH ROSS, R.N., SUPERVISOR OF NURSES, NEW HAVEN HEALTH CENTER, NEW HAVEN, CONN.

OF THE many types of health work open to the nurse, industrial nursing is one of the most appealing and the least satisfying. While it invites and needs the best that the profession can produce, it is rarely that a worthwhile nurse can long remain in the work without damage to her ideals. This is not because it is a pioneer field, but because of the difficult conditions under which the industrial nurse is compelled to work. She is like a child who is being brought up by a host of relatives, each with his own ideas and each jealous of the other's influence. Between them the child has little chance to make good and usually ends by disappointing everyone, herself most of all.

In the spring of 1920, when industrial conditions were still good, I went to New York and took a course in industrial relations, not because I wished to be a personnel manager or the head of an employment department, but simply to find out for myself what policy a personnel department was expected to have regarding public health in general, and the health of the employees in particular, whose welfare was to be its special responsibility in the great industrial system. I listened to many of the most successful personnel men of the country, to labor experts, industrial engineers, psychologists, employers who did and did not believe in the Lynch plan, experts on industrial housing, statistical experts on labor fatigue, and the heads of some of the largest welfare and research departments of this country, and never once were the words public health used. A great deal was said about the safety methods and a little about industrial insurance; but the health of the individual or its effect upon others was as a tale untold. The organization charts that were presented and approved did include nursing service but usually under a department whose head had neither knowledge or interest in a real health program.

This was the condition two years ago. Since that time everything that touches industrial relations has been at a standstill. The nurse within the industry has lost less than have many other workers, but this is because she had little to lose. The emergency hospital and first aid room must be maintained while the factory is in

operation. Insurance laws usually cover this point. The nurse whose task it was to look up the absentees may have lost her position, but that can be considered as a fortunate misfortune. During the last two years there has been no industrial depression among nurses, there are three or four positions waiting for any good public health nurse. It is not that the nurse needs the industry, but that the industry needs the nurse. Before this need can be met, something will have to be done to bring to industry an appreciation of the true value of maintaining good health conditions both within and without their industries. Labor unions must also realize that it is to their advantage to keep the workers in good health, not by paying sick benefits but by careful supervision of the health of their members. Such a program needs doctors and nurses working together with employers and employees, caring for the sick incidentally, but with all forces focused upon maintaining the force in health. What is the nurse's part in this health campaign?

Where Do Orders Come From

To understand the nurse, one must understand the process of her training. Nurses have been trained, like the soldiers, to obey their chief officer, and it is this habit of obedience, that properly used is an asset, when misused results in tragedy. The short sighted boss says, "You can take care of the fellow's hand just as well as a doctor, go ahead and fix it up, I'll stand back of you, what more do you want?" The nurse says "No, it is not my work," but the boss says, "You do it or I will get some one who will." The really intelligent nurse will stand to her guns and refuse to follow a course that she knows is unwise, but the nurse of poor caliber will do as she is told. Even though she may get by with it, such a nurse has placed industrial nursing just one notch lower professionally and someone will have to work just that much longer to make industrial work safe for a nurse.

The nurse who allows herself to act as a detective reporting on the employees who "Play hooky" places herself and her profession at the mercy of the unscrupulous and so violates every professional standard. One nurse after another has said to

me "I can't stay in industrial nursing and keep my self-respect. The money is all right, the hours are good, I love the work itself, but I have no one to help me. No one in the whole plant understands what I am really trying to do. Even Mr. Blank, who seems so interested in the workmen, can't see that I must have a free hand and the backing of the superintendent, if anything is to be accomplished," all of which causes the industrial nurse to feel that she has at present a dead end job.

The late Miss Florence S. Wright, shortly before her death, when discussing the subject of industrial nursing from the point of view of her own experience said: "I cannot go into the factory, much as I enjoy the work because the position that the nurse finds herself placed in is intolerable." Another nurse employed by one of the largest manufacturing corporations of the country in a local plant left because she was classed as an unskilled workman. When she protested she was told that they were sorry but it could not be helped as they could not put her on a level with the foreman. She was, however, expected to do the most confidential type of investigation work and to keep records of the most intimate sort regarding all of the employees. One of the plant managers openly bewailed the loss of this most efficient nurse, saying that she was very valuable to them and it was a great loss to have her leave, but it never once occurred to him that job analysis, or the lack of it, was the cause of their misfortune.

An employment manager once asked me why it was that they could not get a nurse for their factory when they paid more than the standard scale and their hours were the same as those of the organizations doing public health work in the city. The answer was easy for anyone who would look below the surface. Nurses who had been in their employ were then working with the various health agencies of the city for less money because they knew that their work counted for something and was understood by those employing them. Another case for job analysis.

Modern science could well demonstrate to industry what can be done in such a case. A good industrial plant could be set up on modern efficiency methods, with a department

of health and safety (note the sequence of these two words) given its proper place in the organization plan, with the work of maintaining the individual health at its highest possible standard, not as a philanthropy but as a natural part of efficiency measures. The care of the sick should be listed in its correct place as a remedial measure, important because of its direct effect upon the individual workman and indirect effect upon the whole working force. Industrial hygiene and sanitation would

be understood to include measures to protect the workman from all types of communicable industrial disease as well as from a broken shaft or fatigue, from bad ventilation or other mechanical causes. The personnel of such a department would need to be made up of the best safety engineers, doctors, nurses, and research workers. The department should be responsible to the corporation heads and stand side by side with all other executive departments justifying the policies by results only

and, in the language of the factory, *deliver the goods*.

It would be a worth while demonstration for all concerned; but who will take the initiative? We look with hope toward the great industrial insurance company or some of the national health organizations as being in the best position to further such a project. Something of the sort must be done and some standard established for industrial health work if the nursing profession is to give of its best.

Industrial Accidents Can Be Prevented*

Safety Devices and Education Cause Great Decrease in Factory Accidents

By DAVID VAN SCHAACK, DIRECTOR OF INSPECTION AND ACCIDENT PREVENTION, AETNA LIFE INSURANCE COMPANY, HARTFORD, CONN.

PREVENTION of industrial accidents has gone beyond prophecy to fulfillment, statistical data shows. Illuminating nation-wide statistics are lacking, for unfortunately no uniform method of keeping statistics of industrial accidents yet prevails. There are, however, significant—in fact, convincing—statistics available from individual industrial corporations, from insurance carriers, and from government records. A substantial start has been made in practically all types of industries in reducing accident frequency and severity, and the safety movement has thereby gained such impetus that not only can there be no retrogression, but failure to make rapid and steady advance will be impossible. We have many notable examples of what can be accomplished in accident prevention. It would be impossible in limited time to make a comprehensive survey of these, but a few examples in a variety of industries can be given.

Accident frequency and severity rates filed with the National Safety Council for the year 1921 are submitted on the standard accident report form adopted by the International Association of Accident Boards and Commissions, the United States Department of Labor, and the National Safety Council. In making the computations, deaths and permanent disabilities have been weighted in equivalent days lost according to the scale adopted by these organizations.

The S. F. Bowser and Company, Inc., Fort Wayne, Indiana, manufac-

turing oil tanks and pumps, shows the following record:

	1920	1921
Frequency rate	45.1	19.6
Severity rate	1.02	0.59
Average number of employees	1126	982

The Walworth Manufacturing Company, Kewanee, Ill., producing valves and fittings, reports:

	1920	1921
Frequency rate	24.47	10.07
Severity rate	4.91	0.31
Average employees	2580	1249

In the paper and pulp industry, the Kimberly-Clark Company, Neenah, Wisconsin, obtained the following results:

	1919	1921
Frequency rate	35	15
Severity rate	2.75	1.5
Average number of employees	2000	1900

The Texas Power and Light Company, Dallas, Texas, reports:

	1920	1921
Frequency rate	58.6	24.7
Severity rate	20.9	15.9
Average number of employees	830	750

One of the most interesting accomplishments in overcoming a difficult problem in accident prevention work is shown by A. L. Kaems, safety engineer of the Simmons Company, Kenosha, Wis. This company manufactures metal beds, and many of its employees are exposed to the point of operation on punch presses. It required much study and mechanical ingenuity to overcome this hazard. The majority of accidents in this type of industry involves loss of fingers or hands, in many cases causing permanent disability. During the year 1921 this concern has attained a reduction of 66 2-3 per cent in average lost time per man, and of more than 60 per cent in its number of accidents as compared with the year 1920.

The striking results obtained, in the face of such a difficult problem,

must cause the thinking business man to reflect when he reviews the reduction effected by the Simmons Company over a period of three years: 10.50 days per man lost in 1919; 3.90 days per man lost in 1920; 1.29 days per man lost in 1921; 36 fingers lost in 1919; 13 fingers lost in 1920; 5 fingers lost in 1921.

Many of us have been accustomed to think of railroad as one of the most dangerous occupations, and of railroad operation as one of the most difficult places in which to inaugurate successful safety work; yet when a man of vision, zeal, and training attacks the problems of railroad accidents, results follow. This is borne out by the experience reported by R. C. Richards, chairman of the Central Safety Committee of the Chicago and North Western Railway. During the year 1920, sixty-two employees met death, while during the year 1921, the fatalities were reduced to forty-three. The number of injuries during the year 1920 were 7,101 as compared to 4,836 in 1921. In 1920, when this company first instituted safety organization, the fatalities reached 97, and 8,404 employees were injured.

It is interesting to note that with an increase of 15 per cent in the volume of business handled in 1921 as compared with 1914, President S. M. Felton of the Chicago Great Western Railroad reports that accidental deaths in 1921 were 49 per cent lower and the injuries 71 per cent lower than in 1914.

Among industries which give the observer the impression of being most hazardous, steel making must certainly be included, yet in the steel indus-

*Read before the Sixth Annual Industrial Conference of the State of New York, Buffalo, November 21 to 23, 1922.

try we find perhaps the most striking illustration of the fact that industrial accidents can be prevented. Since 1906, the accident prevention work of the United States Steel Corporation has saved 35,000 men from being killed or seriously injured. In the current year, 1922, one year only, the corporation is having 30,000 less accidents involving loss of time beyond the turn. The effect of the corporation's accident prevention work is almost incredible. Think of a plant like the immense South Works of the Illinois Steel Company or the Farrell Works going one, even two months, without a single accident.

Leaving out of consideration the humanitarian viewpoint and the indirect economic value of its accident prevention work, the corporation is saving directly over a million dollars a year. That is to say, the cost of its accidents plus the cost of its accident prevention work, which is about a million dollars a year, is more than a million dollars less than the cost of its accidents alone would be if the rate of accidents prevailing in 1906 were applied to present employment and present accident costs. Charles L. Close, head of the corporation's accident prevention work, said to me recently: "The work is so thoroughly established that it is considered today a part of the manufacture of steel, just as much a process of steel making as is a blast furnace or an open hearth."

Prevention—Financial Gain

In the metal mining industry, we also find proof that accidents can be prevented. The United States Bureau of Mines has stimulated organization of safety work in this industry for several years, and its results are shown by the accident record covering 300 day workers ranging in number from approximately 60,000 to 81,000. Comparing 1920 with 1915, the rate for injuries per one thousand 300 day workers has fallen from 358.18 to 307.60, and for fatalities from 4.25 to 3.48. In 1920, the injured were 14.2 per cent less than in 1919, and the killed were less by 18.8 per cent.

Statistics cited prove that accident frequency and accident severity can be materially affected by safety work.

Proof over a wider range or direct financial gain from accident prevention is furnished by the experience of insurance carriers in the application of experience rating, which undertakes in the case of the individual plant to which it is applied to vary the manual rate for the classification to which the plant belongs, or this

rate as affected by schedule rating of the plant, according to the accident experience of the plant itself. In thirteen states within less than two years there have been 13,000 deviations through experience rating, and nearly 10,000 of these have been in the way of reductions, running as high as over 50 per cent of the manual or schedule adjusted rate. Results over such a wide range cannot be attributed to luck or the more favorable accident experience of less hazardous industries. They must come through a broad extension of increased interest in organized and effective safety work in industry generally. A few illustrations—from the experience of the Aetna Insurance Company will suffice.

A large plush and velvet goods manufacturing concern had been operating without giving any special attention to preventing accidents. Co-operative safety engineering work lessened its accidents to such an extent that experience rating reduced its rate to 31 per cent below schedule rate, from 41.6 cents per hundred of payroll to 28.7 cents.

A logging and lumbering plant with saw and moulding mills by safety engineering work has reduced its rate to 23.6 per cent below manual.

A contracting concern has obtained through its accident prevention efforts a rate of 61 per cent below manual.

A scale manufacturing concern has so reduced its accident frequency and severity by developing accident prevention work as to justify a rate reduction of 25.5 per cent below the schedule rate.

A large machine shop has by similar means obtained a rate of 44.7 per cent below schedule rate.

The increasing extent to which insurance rates are being reduced for individual concerns through experience rating is perhaps the most thoroughly convincing evidence that accidents can be prevented. An employer might be satisfied, for humanitarian reasons alone, to carry on safety work, and might be content if his record showed a reduction in frequency without inquiring too closely as to its effect upon costs, but when an insurance company reduces, through experience rating, the premium rate for a plant, it means that the plant has so improved its accident experience beyond the average for its classification that the reduction in rate is economically justifiable.

The fact that industrial accidents can be prevented is incidentally, but none the less forcefully, attested in two or three other ways. One is

found in the large expenditure of money running into the millions by insurance carriers for accident prevention work which they have carried on for years, and which is steadily increasing in both range and intensity, a work which runs from the inspection of plants for mechanical and physical defects to the stimulation of organized accident prevention effort in every possible way.

Reduced Insurance Rates

Another is the encouragement offered to accident reduction by the schedule rating plan, which undertakes to vary the manual rate down or up by presence or absence of safeguards and safe conditions. Insurance carriers would not expend large sums of money in furthering accident prevention, nor reduce their rates in accordance with the prevalence of safe conditions, were they not convinced that accidents can be prevented, and did they not firmly believe that reducing accidents has not only a humanitarian value to society but also an economic advantage. They could not afford to do so, for whatever the individual feelings of their managers might be, their business must be conducted upon a sound economical basis.

Still a third piece of evidence is found in the remarkable rate of growth of membership in the National Safety Council, and the persistency of that membership in the face of adverse conditions recently prevailing. During the disturbed state of business and industry following the war when industry generally was cutting out all avoidable expense the Council lost only 25 per cent of the 4000 and more membership—membership of industrial concerns, not individuals—which it built up so rapidly during the first half dozen years of its existence solely on the idea that accidents are preventable and this loss was confined chiefly to smaller concerns. I think it will be readily conceded that this affords real proof not only that industrial accidents are preventable, but that they are actually being prevented. It is beyond belief that so many employers would continue, in times when every dollar must be made to count, their support of an organization which undertakes to do nothing for them in the way of direct service but aid them in their accident prevention and associated work, unless they were convinced by their own experience that industrial accidents can be prevented and that the Council's aid actually helped them to prevent accidents in their plants.

Above all, accident prevention work

in any concern must be an essential part of the business if it is to be fully successful. Harking back to Mr. Close's remark, which I have quoted to you, it must be considered a part of the manufacture of the product, just as necessary a process as any other in the plant's operation.

Once the management's real interest is aroused, a comprehensive plan of organizing the accident prevention work must be established to see that the work has its real place in the plant's operation and that it is carried on systematically and intelligently. The methods followed under such organization are practically the same in all industries. The necessary means to the desired end is found in a combination of two factors. The first includes mechanical and engineering improvements. Lack of these is, in many industries and lines of work chiefly responsible for accident severity. They are also an earnest of the management's good faith. Workmen cannot be expected to do their part in avoiding accidents unless it is evident to them that the management is doing its part.

The second factor is organization and education of personnel, workmen, foremen, and superintendents. These two factors are so interdependent that it is practically useless, in most industries, to undertake to reduce accidents to any considerable extent without making use of them both.

In developing the first factor, mechanical and engineering improvements, there are two methods of approach. One might properly be termed the patch work method. When the use of machinery and mechanical apparatus began to replace hand work, machinery naturally was built for production at the minimum cost, and little attention was given to the danger of accidents from exposed gears, set screws, and reciprocating and revolving parts. A great change has gradually come about, but machinery is still turned out insufficiently guarded, and, of course, there is much of the older machinery yet in use. What has not already been safeguarded by the makers must, therefore, be safeguarded by the users, so far as such safeguarding is possible. The same necessity, of course, applies to physical conditions other than mechanical in a plant, when in its construction, lay-out, and equipment insufficient consideration was given to safety requirements.

Actual provision of such safeguards must be approached in a truly scientific manner if real results are to follow their installation. Only a careful

study of working conditions, a painstaking analysis of accidents occurring under them, and a searching inquiry into potential causes of accidents that may not have occurred will determine truly the hazards to which workmen are exposed and indicate the correct means of overcoming them. No remedy can be effective which is based upon a wrong diagnosis.

Conversely, the best diagnosis will be futile unless it is followed by the furnishing of the right kind of remedy. The nature of the safeguard to be provided is as important as the determination of the risk. A safeguard has two functions, that of effect and that of appeal. To fulfill these functions, it must not only be necessary and calculated really to prevent the accident which it is designed to avert, but it must serve its purpose without unnecessary interference with the doing of the work. In a word, it must be practical, wholly practical, and nothing but practical. If a safeguard is impractical, whether in effect or in appeal, it is useless and a hindrance rather than a help to the cause of accident prevention. An employer cannot be expected to continue spending his money for unnecessary safeguards, for safeguards which do not guard, or for those which do guard at the expense of a too material loss in efficiency. A workman cannot be expected to use a safeguard, if use can possibly be avoided when its predominant appeal to him is that of an unnecessary interference with his work.

Enlist Man on Job

There is no better way of assuring that a safeguard will be thoroughly practical, will fulfill both of its functions of effect and appeal, than to enlist the aid of the men on the job, the foreman and the workman. No one else knows so well the true risks of the work involved, the ways in which these risks lead to accident, and the manner in which they can be avoided with least interference with work. There is psychological result of such cooperation, the value of which cannot well be over estimated. If the man on the job feels that he has actually had a real part, even though a small one, in the provision of a safeguard for work which he is doing, or which is being done under his supervision, he is pretty sure to use it or to see that it is used. He comes to look upon it as his guard and to take the keenest interest in its maintenance and use.

The second method of developing mechanical and engineering improve-

ments is found in engineering revision. Of course, the application of safeguards to machinery of faulty design is in a sense engineering revision, but I am referring to engineering revision on a broader and more original scale, engineering revision which includes the design of buildings and working places, their location with special reference to necessary connection with transportation facilities, the provision of ready and safe access to every point where workers must go, adequate and properly arranged lighting and machinery designed from the safety standpoint as well as that of efficiency—the sort of engineering revision which makes everything as safe as possible from the very beginning.

When engineering revision in this sense prevails generally, the ideal not only from the humanitarian but from the economic viewpoint will be reached in this phase of accident prevention work. There is no innate conflict between safety and efficiency. On the contrary, they are largely interdependent, and the wide prevalence of safety engineering in the larger sense will not only tremendously increase results from accident prevention work but it will do this in the most economical way. Referring to machinery, for instance, the logical place to do safeguarding is in the factory where the machine is designed and constructed. Already many purchasing departments of large concerns are having the design of machines checked up for safeguarding before orders for them are placed. The time is coming when not only will every purchasing department do this, but every designer of machinery will have safety in mind in developing mechanical apparatus.

The second factor in reducing accidents is safety organization and education of the personnel. In many industries, this is the more important of the two, for in these only a relatively limited number of accidents are affected by physical and mechanical safeguarding. In all it is of great importance, for despite all the safeguarding that may be possible, even where the highest type of engineering revision prevails, there will be many accidents due to the human equation.

We can, however, in spite of difficulties encountered in endeavoring to remodel the fixed careless habits of some of the present day employees, take encouragement from the fact that safety education in the schools of this country is gradually developing a body of workmen for the future who will have safety as a part of their state of mind. When this generation comes to

man our shops, factories and other working places, organization and education of foremen and workmen will have practically unlimited possibilities.

Remarkable results in accident prevention have been obtained already

despite the largely patchwork nature of remedies applicable under existing conditions, giving ample proof that industrial accidents can be prevented, but they are small in comparison with what will be obtained when engineer-

ing revision in its complete sense and a personnel composed of individuals who, as one result of their education, instinctively think safety and act safely unite to make industry as safe as it is humanly possible to make it.

Conference Board of Physicians in Industry

AMONG the questions discussed at the thirty-fifth meeting of the Conference Board of Physicians in Industry, held November 18 outline for making physical examinations.

in New York City, were dental work in industry, inguinal hernia, and an

Dental Work in Industry

The experience of different members with dental work in industry was discussed and, while some felt that the value of this work had been overestimated, others were of the opinion that it was of growing importance. One case was reported where dental work had been carried on for a few years among a group of 550 employees, among whom no emergency treatments had been necessary during the past year. This was attributed to the prophylactic work which had been carried on among this group of workers.

It was decided that dental work in industry was justified for two reasons: (1) constitutional, in ridding the body of foci of infection; and (2) cosmetic, in improving the appearance of the individual. It is realized that the economic effect is one of major importance, but difficult to measure with any degree of accuracy on account of other influences which must be considered.

Inguinal Hernia

The question of traumatic inguinal hernia was again reviewed in light of the further experience of members. One case of possible traumatic inguinal hernia of recent occurrence was reported. In the experience of the other physicians present no case of traumatic inguinal hernia had ever been known.

It was the consensus of opinion that inasmuch as true traumatic hernia is exceedingly rare and of negligible importance from the standpoint of the industrial physician, the development of inguinal hernia should be considered an occupational disease and compensation should be paid on the basis of aggravation of a pre-existing condition rather than as the result of a definite injury.

Pain encountered has no relation to the size of the hernia sac as suggested, but is related directly to the amount of pressure that the sac makes upon the ilio-inguinal or ilio-hypogastric nerve. This explains why some small hernias are more distressing and painful than others of much larger size.

The fact was also brought out in the discussion that recurrence in operated cases may be due to rupture of the tissues along the line of stitches closing the original hernia. Only close examination will bring this fact to light. Many cases of this type are considered as recurrent hernia at the original site of operation. Another cause of recurrence is due to overlooking a small, indirect hernia which may be coincident with a larger direct hernia. Following operation for the direct hernia, the indirect may increase in size and severity of symptoms and be taken for true recurrence of the direct type.

Examination Outline

The standard physical examination outline developed by the Conference Board of Physicians in Industry early in its work has undergone slight revision as a result of the more extended experience of the members. Such changes were discussed and the revised outlined officially adopted. It is understood that this outline is to be used as a guide by physicians when making physical examinations in order that important matters will not be overlooked. Its adaptation as a form for recording physical findings is purely optional with the examiner.

In the making of physical examinations, it is realized that in many cases and for many purposes, a partial examination only will be necessary and that, barring special cases, the examination would need to consume only an average of from six to ten minutes per person. It is also understood that the procedure may be added to or subtracted from as the peculiar requirements of each industry may make advisable in the judgment of the examining physician. This outline is as follows:

SPECIAL SENSES

- (a) Eyes:
 - Visual Acuity: Right Eye.... Left Eye....
 - Visual acuity of 20/40 or less in both eyes indicates specified employment—Class III, and further investigation.
 - Visual acuity of less than 20/30 in one eye and less than 20/200 in the other with suitable correction indicates specified employment—Class III.
 - A greater disparity in vision of the two eyes indicates need for further investigation.
 - Reading Test: Right Eye.... Left Eye....
 -Size of type.....
 -Distance.....
 - Field of Vision: Right Eye.... Left Eye....
 -Normal or Limited.....
 - Loss of more than one-third of field of vision of both eyes, or loss of two-thirds of field of either eye indicates specified employment—Class III.
 - Color Sense: Ability to match colors and call them correctly.
 - Pupils: Reaction.
 - Puffiness of Lids
- (b) Ears:
 - Drums: Right Ear..... Left Ear.....
 -Hearing Power.....
 -By Watch.....
 - Use Ingersoll one dollar watch at thirty-six inches as normal. Any variation from normal to be indicated by a fraction whose numerator is 36, the denominator being distance at which watch can be heard. Deafness to be indicated by the word "contact." Hearing power of less than one-half normal indicates specified employment—Class III.
- (c) Nose:
 - Septum.
 - Turbinates.
 - Obstruction.
- (d) Mouth and Throat:
 - Condition of teeth.¹
 - Condition of gums.
 - Condition of tonsils.¹
 - Thyroid enlargement.

CHEST EXAMINATION

- (a) Heart:
 - (1) Myocardial test: Effort syndrome. Pulse recording before and after exercise.
 - (2) Blood pressure taken on all cases over forty years of age; others as indicated.
 - (3) Valvular disease, compensated or uncompensated.
 - (4) Arrhythmia.
 - (5) Tachycardia
- (b) Lungs:
 - (1) Inspection—lagging, apical retractions.
 - (2) Auscultation—Eight points to examine closely as follows:
 - Front: Apex of lung—right and left. Intraclavicular space—right and left.
 - Back: Suprascapular space—right and left.
 - Base of lung—right and left.

ABDOMINAL INSPECTION

- Abdomen. Inspection. Abdominal tumors.
- Hernia:
 - Inguinal: complete, incomplete, oblique, direct.
 - Size of external ring—
 - Impulse, present or absent—
 - Femoral hernia. Ventral hernia. Umbilical hernia.
 - Post-operative hernia.
 - Abdominal wall hernia.
 - Spine: curvature, mobility.
 - Ungs: Examined for hemorrhoids, fissures, fistulae, protrusions.
 - Genitals: Examined for varicocele and hydrocele.

CONDITION OF EXTREMITIES

- (a) Lower: Varicose veins; joint mobility; loss of member; deep reflexes; foot strain.

¹All deformities and contagious conditions should be noted in the proper place. Applicants should be rejected on physical grounds only when their employment would make them a menace to themselves, to others, or to property.

(b) *Upper*: Joint motility; loss of member; loss of digits; tremors.
General: Gait, Romberg, Skin.

Height, weight and age to be recorded.
 Suggested classification for conditions of teeth: (1) Good—No repair needed; (2) Fair—Minor defects; treatment advisable; (3) Bad—Serious defects needing immediately corrective treatment.

Diseased tonsils in adult should be removed. Such cases should be followed and removal advised. In absence of other disability diseased tonsils should put the person examined in Class II.

Following questions will give a good background for obtaining important family history information: (1) When did you last consult a physician? (2) Have you ever been in hospital or sanitarium? (3) Have you ever had heart trouble, lung trouble or tuberculosis? (4) Have you ever had tonsillitis? (5) Have you had fits or fainting spells? (6) Are you well and strong? (7) Have any relatives

had tuberculosis? (8) Have you ever had accidents, operations or injuries? (9) Have you weak lungs or heart trouble?

Classification of Physical Findings

Classification of Physical Findings: *Class I.* Physically fit for any work. *Class II.* Physically underdeveloped, or with some slight anatomical defect; otherwise fit for any work. *Class III.* Fit only for certain employment when specifically approved and supervised by the medical department. *Class IV.* Unfit for any employment.

Suggestions, arising out of the experience of physicians in industry who use this outline in their work, would be appreciated by the Conference Board of Physicians.

to ankles. Liver and spleen palpated.
 (12) Genitalia and inguinal canal inspected and palpated.

(13) Applicant faces about and bends forward.
 (14) Spinal and anal inspection and palpation.

(15) Legs inspected.
 (16) Applicant pulls up clothing and feet are examined.

(17) Simple movements of extremities will show any joint involvement.

(18) Blood pressure taken if indicated or on applicants over forty years of age.

(19) Any other laboratory tests indicated. *History*: Questions as to previous accidents, illnesses and operations. Date last visited physician, and cause for such visit.

The details under each of the above suggested steps may be amplified to suit the particular industry. Ordinarily such an examination can be made in five minutes.

ROUTINE FOR WOMEN

(1) Height and weight in ordinary clothing.

(2) (a) Examination of eyes for color blindness. (b) Examination by Snellen Charts of vision, both without and with correction. *Note*: Numbers 1 and 2 can be done before the following by a nurse.

(3) Applicants remove coats, shawls or wraps.

(4) General inspection with applicant standing. Romberg tried.

(5) Applicant sits facing examiner, who is standing and hearing tested with Ingersoll watch. Hair and scalp inspected.

(6) Examiner sits: In the order named, right ear, right eye, left eye, left ear, nose, mouth and throat are examined, with head mirror.

(7) Neck inspected and palpated.

(8) Chest inspected while comparing pulse and counting pulse.

(9) Apex and upper portion of chest percussed and auscultated.

(10) Simple movements of the extremities will show joint involvement.

(11) Applicant removes shoes and feet are examined.

(12) Blood pressure taken if indicated, or on applicants over forty years of age.

(13) Any other laboratory tests indicated. *History*: Questions as to previous accidents, illnesses and operations. Date last visited physician, and cause for such visit.

The details under each of the above suggested steps may be amplified to suit the particular industry. Ordinarily, such an examination can be made in five minutes.

New England Conference *

THE New England Conference of Industrial Physicians has developed and standardized the following method for making routine physical examination of applicants for employment in industry. Inquiry among the members of the Conference brought out the great diversity that marked procedures in this work.

The Conference undertook the preparation of a concise method which as here outlined has been employed by some members of the Conference for several years.

In order to disarm the applicant of any suspicion regarding the purpose of the examination, it is deemed expedient to discuss the value of such examinations, both to the applicant and to the industry, at the time the physical examination is made. It is also felt that the experience of the Conference members has developed a satisfactory examination of female workers which requires little or no disrobing on their part. It should be kept in mind that the use of this outline refers to the examination of the average individual who is in all probability acceptable for industry. In those cases which exhibit defects or diseases it is assumed, of course, that a more detailed examination will be made, depending upon the findings and other conditions surrounding the case. It is felt that the element of time consumed in making examinations is one of great importance. Experience has shown that the attached outline, from step 3 on, can be covered in approximately five minutes. Special cases will require more time; also, the requirements of certain industries or processes within an industry would necessitate a more thorough examination

than here suggested. The detailed outline follows:

ROUTINE FOR MEN

(1) Height and weight in ordinary clothing.

(2) (a) Examination of eyes for color blindness. (b) Examination by Snellen Charts of vision, both without and with correction. *Note*: Numbers 1 and 2 can be done by a nurse.

(3) Male applicants, stripped to the waist and with both feet bare.

(4) General inspection with applicant standing. Romberg tried.

(5) Applicant sits facing examiner who is standing and hearing tested with Ingersoll watch. Hair and scalp inspected.

(6) Examiner sits: Right ear, right eye, left eye, left ear, nose, mouth and throat examined in this order with head mirror.

(7) Neck inspected and palpated.

(8) Chest inspected while comparing pulses. Precordium palpated while counting pulse beat.

(9) Completion of chest examination.

(10) Test knee jerks.

(11) Applicant stands and drops clothing

National Child Labor Program

THE National Child Labor Committee reports field work in seven states in 1922 and legislation in five. Members of the field staff have been engaged in the following fields:

Alabama—Study of laws affecting children and recommendations for legislation for the state child welfare department.

Iowa—Study of juvenile street work in Des Moines, Davenport, Cedar Rapids, and Mason City.

Kentucky—Cooperated with the Children's Code Commission in the drafting and introducing of bills, especially the child welfare commission bill. Brought previous study up to date.

Michigan—Study of child labor in the beet fields. Report will be completed shortly.

New Jersey—Study of the health problems of the Girls' Continuation School in Newark, supplementing study of last year.

New York—Cooperated with Na-

tional Child Health Council in the health study in Erie County, New York.

Ohio—Study of child labor in the onion fields, in conjunction with the Institute for Public Efficiency and Department of Industrial Relations. Report will be completed shortly.

Virginia—Cooperated with the Children's Code Commission on important child labor and compulsory school attendance laws which passed.

Short investigations were also made in New York, Nebraska, North Carolina, and legislative assistance was given in Rhode Island.

Eleven states met in regular session. The most important state legislation on child labor and kindred subjects is briefly summarized as follows:

Kentucky adopted several constructive educational measures and enacted a law to create a child welfare commission to continue the work of the Children's Code Commission.

Maryland established a new bureau of child hygiene in the department of

*For purposes of comparison and comment there is presented herewith parallel work looking toward standardized practice in physical examination developed by industrial physicians in New England.

health and provided for vocational supervision for mentally retarded children.

New York enacted a children's court act; made changes in the administration of mothers' pensions, in the procedure for issuing employment certificates, and in the domestic relations law concerning child placing. The compulsory education law was amended, making it more enforceable.

Rhode Island raised the educational requirement for employment certificates. A 48-hour law for children under 16 was defeated.

Virginia extended the 14-year age limit to include all gainful occupations except agriculture; raised the age limit for street trading; prohibited night work in street trades and street permits for boys 12 to 16; set a 16 year age limit for boys and 18 for girls for work in specified occupations. Hours were reduced from 48 to 44 for children under 16 in all gainful occupations except agriculture, with an exemption for canneries during vacation. School attendance was made compulsory from 8 to 14 years during the entire school year.

The mothers' pension act was extended and legislation relating to juvenile courts, child caring institutions, etc., was also passed. A children's bureau was created within the state board of public welfare.

The action of the trustees in authorizing a campaign for a child labor constitutional amendment determines in part our immediate future policy, states *The American Child*. "It is nevertheless necessary to continue active cooperation with our associates in backward states that are attempting to secure advanced legislation, and we conceive this to be in harmony with the purpose of the Board. During the past year sixteen states called on the committee for general surveys, special studies, or legislative assistance which we could not undertake because of limited staff and funds. The recommendation of an increase in our annual budget from \$100,000 to approximately \$185,000 contemplates the expenditure of practically the entire additional sum in the extension of our field work and publicity for the constitutional amendment and our state activities."

The plaintiff was a stone cutter who was put to work at a defective machine surfacing stone. He had not been doing work of this sort for a time and the muscles called into play were soft and became sore, also the defective machine required great effort to operate. He suffered pain but continued to work because "he had a family to support and was very reluctant to cease remunerative employment. After several weeks he noticed that the pain was no longer as acute as it had been at first, but the shoulder was becoming stiff. . . . He also noticed that his shoulder blade would leave its position in the back and would stand outward when his arm was raised in an upward position." It was found that "the muscles which control the shoulder have become atrophied through degeneration of the nerves supporting them, and that "there nerves under the heavy strain required by the work of this machine, as aforesaid, were subjected to excessive traction and became, for all practical purposes, dead." The Court held that these injuries were not accidental under the Compensation Law. "The Compensation Act was not designed to cover cases where injuries result from ordinary overwork or too long continued effort without any sudden or violent rupture or collapse of some physical structure or function of the body." —*Young v. Melrose Granite Co., 189 N.W. 426.*

Recent Compensation Decisions

BY DOROTHY KETCHAM, DIRECTOR, SOCIAL SERVICE, UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

IN THE case of a watchman sixty-three years old, while making his rounds suddenly feeling a sharp pain in his knee which caused him to fall, the Supreme Judicial Court of Maine, June 19, 1922 has held that a finding of consequent injury received in the course of and arising out of his employment was warranted within the Workmen's Compensation Act. "The incident happened in the early morning, about 1 o'clock of June 8, 1921. The claimant was then, and had been for many years, employed as a night watchman. . . . His duties began at 6 o'clock at night and continued until 6 o'clock in the morning. They included the hourly winding of the clocks placed in different parts of the mill. On this night he had regularly made his rounds, each time climbing seventy-two steps. He was upon his rounds and had just climbed a flight of stairs and proceeded about ten feet inside a room, walking on a level floor, when, as he describes the occurrence, "I felt a little pain in my knee below these cords. I don't know whether it was in the knee or what it was; it all gave out. . . . It went out from under me as quick as a flash;

then I went down. . . ."

The decision of the court was as follows:

No testimony was introduced by the employer or the insurance carrier. Upon the undisputed testimony the chairman awarded compensation, and the respondent appeals.

That the injury was received in the course of the employment is evident. The claimant was at the time engaged in the work which he was employed to perform; that is the test.

Did the injury arise out of the employment? This question must alone be answered in the affirmative. The chairman has so found upon the undisputed facts. We think that the finding is warranted.

Here there must be some causal connection between the conditions under which the employer worked and the injury which he received. That the sudden cramp and instant fall of the claimant was caused by the performance of his duty in hourly making his rounds and climbing the stairs may properly and reasonably be found; it was traceable to his work.—*Webber's Case, 117A, 515.*

THE Supreme Court of Minnesota, July 14, 1922 declared that the Workmen's Compensation Act does not cover injuries resulting to the muscles and nerves through a too long continuance at a task that is too heavy for the employee, and where there is no sudden or violent event producing at the time injury to the physical structure of the body. Only an outline of the situation will be given.

THE Supreme Court of Oregon, July 29, 1922 held that an appeal does not lie under the Workmen's Compensation Act from action of the Industrial Accident Commission, in the designation of a physician and hospital for an injured workman. The matter is entirely within the commission's discretion and is not mentioned in the act as a measure for which the right of appeal is granted. "While in this particular instance the plaintiff selected a competent surgeon, there would no doubt occur many instances where ignorant workmen, if allowed to select at will a surgeon to attend them, might fall into the clutches of unskilled quacks whose ministrations would prolong their disability and thereby inflict unnecessary suffering upon them and an increased financial burden upon the compensation fund. For these reasons the law has properly placed the selection of a physician upon the commission, and from the honest exercise of the discretion so given there is no appeal."—*State v. State Industrial Accident Commission, 208, Poe 716.*

The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents

Methods of Determining Malnutrition*

Comparison of Pelidisi, Wood Height and Weight, and Dunfermline Methods

By S. JOSEPHINE BAKER, M.D., DIRECTOR, AND J. L. BLUMENTHAL, M.D., BOROUGH CHIEF, BUREAU OF CHILD HYGIENE, NEW YORK CITY.

THE undue prevalence of under-nourishment among school children which has been evident during the past five or six years has resulted in an extended interest in methods of determining degrees of nutrition, as well as methods for the prevention or correction of this condition. The present status of our standards for determining undernourishment is not wholly satisfactory. The simplest method, and the one that is most generally used, is that of determining the relative weight for the height of the child. Age, in this case, may or may not be taken into consideration. It is conceded that such a method offers a readily available and rough test of a child's nutritional condition. It is, however, unsatisfactory in a certain proportion of cases, and cannot be considered scientifically adequate.

Various authorities have published standard tables of height and weight of children. These have been based upon groups of children living in a city environment and rarely take into consideration suburban or rural conditions or the enormously important racial factors which affect physique. Authorities also vary in their relative determination of the nutritional standard. The Child Health Organization, which has published the height and weight tables compiled by Dr. Thomas D. Wood of Columbia University, estimated that any child falling 10 per cent below this weight for his height is undernourished. Dr.

W. R. P. Emerson, Professor of Pediatrics at Tufts Medical College, Boston, states that a child who is 7 per cent below the given weight for height cannot be considered properly nourished.

FIG. 1—An easily contrived apparatus for taking measurements under the "pelidisi" system. The child sits erect on the seat provided while the sitting height is taken. Both legs hang free, and the occiput and sacral portions of the vertebral column are in firm contact with the measuring rod.

Contrasted with the group who depend upon relative weight for height as the determining factor of nutrition, a large group of medical and public health authorities have based their standards upon the results of a complete physical examination of each child, including the estimation of height and weight. Recently, a third

method followed by Dr. Pirquet, of Vienna, and called by him the "pelidisi" has been attracting attention in this country. The literature on the subject is not extensive, but the reports from the Pirquet clinic seem to show that it has been a satisfactory method under the conditions which obtain in the work there. Recent literature has shown that the method has been, and is being, tested out in this country. The reports, however, are not universally commendatory. In fact, the general impression gleaned is that the system does not seem suited for use with the average child, as found under conditions existing in the United States. These conditions are, of course, in marked contrast to those which obtain in the starved or semi-starved children included in the group under Dr. Pirquet's observation. Reference is made to his writings, and to other literature on this subject, for the exact details of the pelidisi method. Briefly, it may be said to be based upon the relation of the weight to the sitting height of the child, with an evaluation of the standards of nutrition on a scale of 100; 93 being considered the minimum normal, anything below that indicating an undernourished condition.

During the winter of 1921-1922, an experimental study to determine the relative values of these three most prominent methods for determining nutrition was made at P. S. 43, Borough of Manhattan, New York City. This school is in a fair residential section of the borough, and covers the grades from kindergarten

to 8b. The children attending it are representative of many racial groups of the city. There is in this school no predominating foreign race group. The social conditions in the homes

procedure recommended by the originator and publisher of these tables, a child 10 per cent underweight, for his height and age, was considered undernourished.

physical examination or by any other method. It consists, briefly, of dividing the children into four groups according to their degree of nourishment. These groups are distinguished as follows:

- (1) *Excellent*.—Means the nutrition of a healthy child of good social standing.
- (2) *Good*.—Refers to a child whose nutrition falls just short of the above standard.
- (3) *Requiring Supervision*.—Refers to children whose nutrition is on the borderland of serious impairment, and who require supervision and care.
- (4) *Requiring Medical Treatment*.—Children in this classification have their nutrition seriously impaired, and need constant medical oversight.

With the "pelidisi" system it was soon found that great care must be exercised in order that the tests might be considered at all accurate. It is evident that great care must be used to see that the children are properly placed on the measuring apparatus. If a child does not sit erect while the sitting height is being taken, differences of one-half to one inch will constantly be noted. The children must be kept under constant observation by the person taking the measurements in order that he may be sure they are sitting squarely on the seat provided, with both legs hanging free, and with the occiput and the sacral portion of the vertebral column firmly

Comparison of the Pelidisi, Dunfermline, and Wood height and weight scales for malnutrition in school boys.

of the children are those of the wage-earning class. No excessive poverty is to be found but, on the other hand, the incomes of the families rarely rise above the amount actually needed for maintenance.

Three Prominent Methods

Dr. Jacob Burstan, medical inspector assigned to this school, made all the examinations. In all, 1,814 children were examined, the same children being used as a basis for the three studies; that is, each child had his nutrition determined by the three methods indicated. The methods used for determining nutrition were:

(1) Complete physical examination. This method included weighing and measuring the children, but such height and weight data were taken as confirmatory indication of proper nutrition or its lack, rather than as a final determining factor. The factors taken into account were the general appearance of the child, condition of the skin, subcutaneous tissues, mucous membranes, and musculature, the vigor or listlessness which appeared in the child's facial expression, carriage, posture, movements, voice, interest and attention, or any other physical condition which indicated a normal or abnormal physical status. The results of these examinations were recorded according to the Dunfermline scale.

(2) Estimation of relative weight in relation to height, as determined by tables prepared by Dr. Thomas D. Wood, published by the Child Health Organization. In accordance with the

(3) Pelidisi, or Pirquet method, using specially prepared apparatus. Estimation was made in each case of the child's "pelidisi," a standard of 93 being taken as the minimum determination of adequate nourishment.

In all, 1,814 children were examined by each of the above methods—1,147 boys and 667 girls—and the results were recorded by both the English

Comparison of the three scales for malnutrition in school girls.

and metric systems of measurement.

The Dunfermline scale, noted under No. 1 above, originated with Dr. Alister Mackenzie, of the Carnegie Dunfermline Trust, Dunfermline, Scotland. It is in no sense a method of determining nutrition, but offers an easy usable scale for recording the degree of undernourishment found after

in contact with the measuring rod. The child's hands should be placed in his lap.

The apparatus used in the present study (Fig. 1.) was specially devised by Dr. Blumenthal and cost, in all, not over three dollars. A stool was secured with a seat not too wide, so that the knees of even the youngest

children could bend at the rim of the seat and allow the legs to hang free. The legs of the stool were trued so that the seat was level and about sixteen inches from the floor level. The stool was then firmly secured to the floor so that it could not be moved about, and so that each child's measurement could be taken from exactly the same position. A yard stick was secured with the metric system of measurements on one side and the English system on the other. To this, an ordinary carpenter's wooden square was fastened by means of spring clips so that the longer arm of the square projected at right angles to the measuring rod while the short arm traveled up and down on the narrow surface of it. Parallel with the longer arm and exactly on a level with the lower surface were tacked two strips which projected over the measurements on the measuring rod and served as indicators in measuring. The measuring rod itself was fastened directly to the upper surface of the seat of the chair in the center of the back and perpendicular to it. It was fixed to the wall so that it could not readily be displaced. The entire apparatus occupied so little space that it was never found in the way. The lower surface of the horizontal arm of the square rested on the highest portion of the skull of the child, and the measurement was then taken by one observer for the metric measurement, and by an observer on the other side for the English. These measurements were immediately transcribed to the tabulation sheet and the "pelidisi" worked out therefrom after the child had been weighed. Variations of from one-quarter to three-quarters of an inch were noted by supervisors until the observers had been thoroughly instructed and paid strict attention to the position of the child and the exact measurements on the ruler.

Table 3 shows that the age groups were fairly evenly distributed. In the 15-16 year groups there were so few children that it was not thought wise to include them in the percentage tables. This lack of children in the age groups mentioned is in accord with the common custom of large numbers of children leaving the elementary schools when they reach the age of fourteen years.

Table 1 shows conditions of malnu-

15 years	72	21	93
16 years	18	9	27
Total	1147	667	1814

trition found, as determined by the three different methods. It will be noted that the results based upon the height and weight tables show a lesser incidence than the physical examination method. The "pelidisi" of 93 and under, however, shows a largely increased evidence of undernourishment, if based upon this method. For this reason a "pelidisi" of 92 and under was also used, the results in such case more nearly approximating the results with the height and weight tables, and being slightly less than those obtained as a result of physical examination.

Tables 2 and 4 are those of racial incidence, and are based upon the nativity of the mother. Some difficulty was experienced in obtaining this information, but it is felt that sufficient was secured to indicate the general racial distribution with accuracy. By far the largest race group was that of the United States, 33.6%. Next largest was Ireland, with 10.4%; Italy,

9.2%; and Russia 6.9%. The incidence of undernourishment as shown in comparison with the race groups is indicated in Table 4, based upon physical examinations recorded by the Dunfermline scale. It is interesting to note that the greatest percentage of undernourishment was found in children of German stock, 34%. Ireland was second, with 31.5%; England third, with 30.0%; Poland fourth, with 26.5%; and the United States fifth, with 24.4%. The Italian group showing the lowest proportion of undernourishment, 13.7%.

Table 5, which gives the results of an analysis of existing malnutrition by age groups, shows some marked variations between the sexes in the various years. In general, however, the variations seem to be greater between the two sexes when the degree of undernourishment is based upon the standards of the Wood tables or the "pelidisi" method than when it is determined by physical examination, graded by the Dunfermline scale.

Conclusions from Survey

This survey would seem to show that:

(1) The determination of degrees of nourishment by means of the height and weight standards according to Dr. Wood's tables shows a lesser incidence, 22.2%, than the results of the complete physical examination recorded by the Dunfermline scale, 25%.

(2) The "pelidisi" of 93 and under shows an excessive percentage of undernourishment that does not seem to be warranted either by the physical examination of the children or by the estimation of their nutrition by the height and weight method, resulting as it does in an average of 33.5% for

NOTE.—The 15 and 16 year groups are eliminated from table because of small number of children in these groups.

both sexes. The "pelidisi" of 93 and under, with a total of 22.3 for both sexes, more nearly approximates the condition of undernourishment found by the height and weight tables of Wood, but is less than the total of 25% found by the physical examination method.

(3) The complete physical exami-

nation of each child, using the Dunfermline scale as a method of recording the findings, affords a method based upon scientific knowledge and trained medical opinion. The fact that the result of these examinations showed that 25% of the children were undernourished, while the height and weight tables indicated an incidence

of 22.2%, and a "pelidisi" of 92 and under showed 22.3%, would seem to indicate that physical examination of children discovers some cases of undernourishment which may be overlooked by other methods. It also indicates that a complete examination of the children is possible under the conditions which obtain in school life.

Cooperative Study of Institutional Dietaries*

Correlation of the Height-Weight-Age Ratio With the Dietary

BY ELIZABETH C. SPRAGUE, PROFESSOR OF HOME ECONOMICS, UNIVERSITY OF KANSAS, LAWRENCE, KANSAS

THIS study illustrates the possibility of cooperative research between schools, institutions, and other agencies. In this instance the cooperating agencies were the Kansas State Board of Administration, the State Training School, the home economics department of the state university, and the Child Hygiene Division of the Kansas State Board of Health.

In the spring of 1919 the newly appointed superintendent of the institution for the feeble-minded, now called the State Training School, Mr. Wylie W. Cook, wrote to the state board of administration asking them to send one to advise him as to the dietary, saying that he was not satisfied with the appearance of the inmates.

The result was that the author, enlisting the services of Dr. Florence Brown Sherbon, chief of the Child Hygiene Division of the State Board of Health and Miss Ora Webb, then a student but later an instructor in the department of home economics, spent three days at the institution investigating conditions. The following data were secured:

The steward's records of the food issued during the previous ten months.

The kitchen records of the food used during the previous twenty-eight days.

The kitchen records of the food used during two days of the investigation.

The height-age-weight ratio of 467 inmates. For a variety of reasons 75 were not examined and 70 were "dwarfed" so that they could not be classified.

Calculations of the average per capita food consumption and its nutritive value were made using the accepted methods.

During the following twelve months the inmates were regularly weighed each month and the weight sheets sent to the Division of Child Hygiene for tabulation and correlation. At the end of the twelve months, Miss Viola Anderson and Miss Ora Webb, instructors in the department of home economics returned and made a second study of the dietary duplicating the procedure used in the first.

The steward's records of the food purchased and the supplies issued to the kitchen and bakery gave a fair estimation of the average per capita consumption during the ten months period. The able bodied were fed in the main dining room, a small group was confined in the hospital, and about one-third of the whole group was not allowed to leave the wards at all. Certain variations were made for each of these groups. In order to show the effect of these variations on the nutritive value of the food provided for the different groups an estimate was made of the food served in the inmates' dining-room, in the wards, and in the hospital during two days of the visit (Saturday, May 24 and Sunday, May 25). The data secured from the kitchen records for the twenty-eight day period served to show the frequency with which certain foods were used as this was taken from the tri-weekly steward's issues.

In all cases the data are for the food furnished with no statement as to the amount wasted. A theoretical deduction of 10 per cent for waste would seem high in this case.

According to the steward's records covering the ten months period the food yielded per capita per day, 75

grams of protein, 60 grams of fat, 457 grams of carbohydrate, and 2,672 calories. These figures are rather low, but it is to be remembered that about 20 per cent of the population consisted of children below the age of 14. Calculated per man per day it approximated 85 grams of protein and three thousand calories, which may be regarded as a fair allowance for this class of people.

The most striking facts are the large proportion of both protein and calories that were furnished by cereal products and vegetables and the small proportion furnished by meats. It is unusual to find as little as 10 per cent of the total cost of food expended for flesh foods, yielding only 3 per cent of the total protein and less than 2 per cent of the calories. In American dietaries the average expenditure for meat is 33 per cent of the total which usually yields about one-third of the protein and 20 per cent of the calories.

The cereal foods supplied 58 per cent of the protein and 54 per cent of the calories. Of the amount spent for vegetables a very large proportion (16.5%) was used for canned vegetables, mainly corn and peas, while the cost of the fresh vegetables was low. In this group i.e. the vegetables, a mere readjustment of the expenditure might materially improve the nutritive balance.

The expenditure for milk and for the proportions of protein and calories yielded by it were liberal. However, as will be shown, the distribution of the milk was very unequal so that the major part of the inmates, those eating in the dining-room, were consuming a very unbalanced diet with too large a proportion of cereals and legumes and without the proper protective foods.

The system of feeding the inmates

*The full data of these studies are obtainable in a bulletin, "A Study in Nutrition of the Inmates of the State Training School, Winfield, Kansas," issued by the Kansas State Board of Administration, Topeka, Kansas.

provided three meals a day. The inmates were divided into three groups: (1) those men, women and children able to go to the dining-room, a total of 429; (2) those confined to the wards (164); and (3) those in the hospital (39). In the latter two groups a few able bodied inmates were detailed to act as assistants. The following was a typical day's menu in the dining room:

BREAKFAST			
Stewed raisins	Gravy	Rolled oats	Coffee
LUNCH			
Bread	Oleo	Peas and corn	
SUPPER			
Vegetable soup (tomatoes, peas and corn)			
Bread			Tea

Milk was allowed for coffee each morning and one gallon was served at each meal for the smallest children in the dining room.

For the wards the menu for breakfast and dinner was the same as that served in the dining room except that about eight gallons of milk were served in addition at each meal. In the evening only bread and milk (twenty-five gallons) were served in the wards. This liberal use of milk showed a marked influence on the nutritive value of the diet.

For the hospital group the food was very similar to that served in the dining room but there were many additions. Nine gallons of soup were furnished per day for thirty-nine people.

The influence of the more generous food allowance for the ward group appears in the following table. The difference between the average per capita consumption during ten months and the typical consumption among the inmates is also apparent.

The greater liberality of the diet on

were confined to the wards and hospital. In the food served in the dining room 87 per cent of the protein and 88 per cent of the calories were furnished by cereal products, including bread and seed vegetables; and 8 per cent of the protein and calories by milk. In the wards and hospital on the other hand 39 per cent of the protein and 31 per cent of the calories were furnished by milk and 58 per cent of the protein and 64 per cent of the calories by cereal products and seed vegetables.

Almost all of the nutrients supplied by the cereal products were yielded by white flour, chiefly in the form of a

considerable improvement in the diet. The figures show an increase in the amount of all animal food served from 12.6 per cent to 20.1 per cent; an increase in the milk allowance to about one and one-third pounds per person per day and a decrease in the cereals from 54 per cent to 45 per cent of the total diet. The character of the vegetable supply was changed by the greater amounts of cabbage, tomatoes, and so on from the large garden which had been planted in the summer of 1919, but the seed vegetables were still used liberally.

Both groups were given sufficient food. No serious deficiency in the type

COMPARISON OF PER CAPITA FOOD CONSUMPTION IN THE FIRST AND SECOND STUDIES.

	10 months' period. (a)		1919, (b) Typical day (May 2).	Typical day 1920 (June 2).		1920. Typical day (June 9).	
	1919, grams.	1920, grams.	Dining room, grams.	Wards, grams.	Dining room, grams.	Wards, grams.	Dining room, grams.
Protein	75	98	66	83	84	85	90
Fat	60	88	38	60	92	75	60
Carbohydrate	457	463	424	421	476	385	467
Calories	2,672	3,042	2,309	2,561	3,394	2,880	2,773

(a) The figures for the ten months' period are higher, because the food for employees, which was more liberal, is included in this calculation.

(b) Record for May 25, 1919, omitted from this comparison, being Sunday, on which day the diet was always more liberal.

very light, soft, unevenly baked bread. The only leafy vegetable furnished the inmates was cabbage, either fresh or in the form of kraut. The low fat content was due to the fact that so little meat was used, that so little fat was used in cooking, and that oleomargarin was served at table only once a day and less than one-third ounce per capita allowed then. There was a very objectionable monotony of

or quantity served in the dining room was shown to result from the uneven distribution of food between the wards and the dining-room as had been the case in 1919. The milk allowance for both was liberal, though it was still unevenly distributed. Meat was given in larger amounts and more frequently. About one-fifth of a pound of meat per person per day was now allowed. The fat had been increased from sixty grams to eighty-eight grams per day. The comparison of the food consumption in the two studies is given in the above table. The more liberal diet in 1920 is obvious as is the more equal distribution of food between the two groups. The day May 25, 1919, is omitted from this table as no Sunday was included in the survey in 1920.

While it may be said that the dietary was considerably improved the conditions were still far from ideal. The same monotony of diet prevailed, the same foods were still used for the noon and evening meals and these foods were still too soft.

These results, especially when taken in connection with the weight findings seem significant as showing what may be accomplished under scientific management.

In May 1919 all inmates who could be placed upon the scales and who could stand upright were weighed and

SUMMARY PER CAPITA FOOD CONSUMPTION.

	May 24, 1919			May 25, 1919		
	10 Months Period	Dining-room	Wards	Dining-room	Wards	
Protein	75 grams	66 grams	83 grams	102 grams	98 grams	
Fat	60 grams	38 grams	60 grams	53 grams	60 grams	
Carbohydrates	457 grams	424 grams	421 grams	460 grams	536 grams	
Calories	2672	2309	2561	3325	3081	

the 25th was due to the fact that it was Sunday. Larger quantities of beans were provided; also, gingerbread, crackers, and a cornstarch pudding were added.

The detailed data showed how large a proportion of the protein and energy was provided by the legumes, white wheat flour and other cereal products with the great lack of protective foods. It was, however, by studying the distribution of the foods between the dining-room and the wards that the deficiency became most apparent. While a fair amount of milk was provided, by far the largest part of it was consumed by one class alone, that is the low grades who

diet, due not only to the use of the same foods on successive days but to the use of the same foods at successive meals. It was the custom to use the same foods, already monotonous, for the noon and evening meals. There was an entire lack of hard foods requiring mastication.

Suggestions for improvement based upon the results of these studies were made to the management. At about the same time in the following year a second visit was made to the institution and the records again studied, using the same methods as before.

It was found that many, though not all of the suggestions had been adopted and that as a result there was

their heights measured. A weight chart was compiled which included the normal weight for each individual, the weight at the stated time, columns for each of twelve successive weighings, the occupation and the general condition of health as estimated by the attendants.

A certain number of those weighed and measured were so dwarfed, mis-

The ages of the inmates varied from five months to 71 years. For purposes of study they were classified by ages into four groups: 0 to 15 years, 16 to 30 years, 31 to 50 years and 51 years or older. There is no way to determine how much the class of people examined in this instance may normally vary from the average standards. No attempt was made to

As a whole, the appearance of the inmates indicated malnourishment. The emaciation of many, and the soft unwholesome fat of others; their sallowness, the prevalence of constipation, the history of outbreaks of pellagra, and the general ravenous behavior in the dining room all indicated wrong feeding. The steady decline of the height-weight-age ratio with the age of the inmates is one of the most significant findings.

The age group "0 to 15 years" showed 16 per cent were more than 10 per cent below the average; "16 to 30 years" showed 42 per cent below the average; "31 to 50 years" showed 54 per cent below the average; "50 and over" showed 68 per cent below the average. The average for the entire group showed 43 per cent who were more than 10 per cent below the average. It would be presumptuous to attempt to explain this without a more detailed inquiry into actual physical conditions. However, three probable factors may be mentioned for the suggestive value they may have: (1) continued residence, eating year after year of a monotonous, unbalanced diet; (2) the cumulative effect of uncorrected defects, particularly bad teeth; and (3) the cumulative effect of chronic toxemia from constipation.

1920 Weight Findings

At the end of the year those individuals whose records included twelve consecutive monthly weighings were tabulated. Of the 467 who were weighed in 1919 only 397 showed no break in the weight record. These were grouped according to ages as at the beginning of the study.

While there are some irregularities and some unexplained showings, one may on the whole say confidently that the weight of the entire group was markedly affected by the changed feeding and that their general condition was for the better.

The actual mass gain was most marked in the group which showed the greatest departure from the normal at the beginning of the study, viz. the oldest group. This group of 22 individuals gained an average of 10 pounds each during the year and lowered their percentage if individuals who were more than 10 per cent under weight from 63 per cent to 50 per cent. However, this group did not then approximate average normal weight of 140 pounds each, when this group averaged only 121 pounds at the beginning and 131 at the close (Plate 1).

The age group, 31 to 50 years, com-

The Kansas State Training School nutritional study was checked at the end of one year and the results of the improved dietaries are shown in the graph.

shaped or deformed that their height-weight-age ratio did not fall within any table of averages. These were classified by the term "dwarfed" and were not figured in the averages. Many could not straighten up, so habitual has this stoop become. For this reason the heights are generally too low. This gives the height-weight ratios better showing than deserved.

make a detailed physical examination of any individuals. There seemed to be little active illness, though constipation was said to be prevalent. From the cursory review as they passed across the scales, the investigator received an impression of many adenoid facies, many cases of strabismus, neglected refraction and a very striking need for dental work.

prised 128 individuals of whom 62, or 48 per cent, were more than 10 per cent underweight at the first weighing. This was lowered to 52, or a total of 40 per cent. This group gained an average of $8\frac{1}{2}$ pounds each but still lacked $2\frac{1}{2}$ pounds of reaching a normal average. These individuals should have averaged 130 each according to their respective heights and ages whereas they averaged 119 pounds at the beginning and $127\frac{1}{2}$ at the end.

The age group, 16 to 30 years, comprised 187 individuals who had gained an average of more than six pounds each by March but lost an average of one pound each during April and May. The percentage of underweight individuals in this group was 31 per cent at the beginning and 26 per cent at the close, calculated on a basis of no gain in height. Since some of this group probably did gain in height their percentage gain over the normal or expected gain would probably have been small.

The youngest group, 15 years or younger, gained an average of ten pounds each. These were all growing children and any estimate of actual improvement in their condition must

take into consideration their expected rate of growth. Accordingly the expected gain in both height and weight was figured for each child and the result compared with the final figures at the end of the year.

This age group in the beginning, numbered 128 individuals who showed only 16 per cent under weight. Only sixty of these completed the year's weighings and this sixty must have been the physical culls as 40 per cent of these were underweight at the beginning as against 16 per cent for the entire age group. The better children were probably returned to relatives and friends or broke the weight record by visits and paroles.

Allowing for average gain in height and weight, this group showed 20 per cent who were more than 10 per cent underweight at the end of the year as against 40 per cent at the beginning. There was a group of 8 individuals in this class who were excessively overweight, averaging 20 per cent overweight per individual. This brings up the general mass average rather more than the entire group merits and leaves them close to a normal mass showing.

ty-seven glasses and one paper cup were examined in this way and the germs identified. This was considered a fair test under normal conditions of practice.

For purposes of contrast a swab from a glass and one from a paper cup were developed in a glass petri-dish, a definite separation existing between the two. The swab from the glass developed 150 colonies; the swab from the paper cup which was found on the top of the stack on the fountain developed only nine colonies.

Of the twenty-seven glasses and one paper cup cultures only two cultures from glasses were sterile, and these were found only at fountains where the dispensers did not wash the glassware during rush hours. Several glasses and the paper cup showed presence of dust-carried organisms only, the harmless type of germs. Germs of putrefaction were found on two glasses, and on two other glasses both putrefactive and dust-borne germs were found.

On nine glasses disease germs were actually found either alone or mixed with dust-borne or putrefactive germs. These were of two types commonly found in noses and throats of persons suffering with sore throat or bad cold.

Main facts brought out by the investigation were: Forty per cent of the glasses examined were actually infected with disease germs. An additional twenty per cent were really dirty or infected with germs of putrefying matter. It was really safe to drink from only the remaining forty per cent of the glasses and less than seven per cent of them were sterile. The paper cup was found to have on its rim only a small number of harmless germs though it had been standing on the back-bar for an indefinite period. Sterile glasses were found only at fountains where a negro was employed during rush hours to wash the glassware in hot water and soap.

School health work has accomplished the following in Randolph County, Ind.: Over 80 per cent of the 5,846 school children have been medically examined; a nurse has been assigned to see that defective children receive medical aid; twenty-three weighing and measuring scales have been put in the schools and over two hundred underweight children are given milk. The county superintendent reports only four deaths during the entire school term and that no school was closed during the term for contagious disease.

Dirty Glasses As Germ Carriers

INDIVIDUAL paper cups or glasses thoroughly washed in hot water and soap are the only guaranty to a germ proof fountain service, investigation in Montgomery, Ala., by the state board of health has revealed.

In the old days when the idea of disease germs on drinking cups was a novel one, it became the custom to drink left handed or near the handle in an effort to avoid contamination. The collapsible drinking cup became a favorite at picnics and was even passed around among friends, "For," states C. A. Abele, director of inspection, Alabama state board of health in *The Soda Fountain*, "what were a few germs between friends?"

It is estimated that there are approximately one hundred thousand soda fountains in the United States which give opportunity for the wide spread of disease. Most important in transmission by this means are common colds and tuberculosis.

The evolution of glass washing at soda fountains is interesting. Formerly the dispenser "washed" his glasses behind an ornate marble fountain in a bucket under the counter in which the water was changed once daily. As business grew and fountains were improved washing basins

were built into the fountain; later a continuous flow of water was installed; still more recently the pressure spray was introduced. In the most modern fountains, however, glasses are now sent to the rear for scrubbing after each use.

To gain first hand information as to contamination from soda fountain glasses the Alabama state board of health recently investigated conditions in Montgomery. They found all sorts of fountains, some using soap and hot water to clean glasses, some using metal drinking cups, some equipped with sterilizers, some with glasses merely rinsed and flushed over a spray, and one fountain which occasionally used paper cups.

Procedure was for two men to enter the soda shops during rush hours in the afternoon, quietly explain their business to the proprietor, and request permission to culture several glasses from the bar—ready for service of drinks. Cultures were taken from the rims of the glasses with sterile cotton swabs. These swabs were then streaked on culture media on which the germs might grow, the plates were numbered and brought to the laboratory for incubation, and the germs examined the next day. Twen-

Health at Columbia Institution for the Deaf

Not Chance But Systematic Health Insurance Method Safeguards this Student Body

By PERCIVAL HALL, PRESIDENT, COLUMBIA INSTITUTION FOR THE DEAF, WASHINGTON, D. C.

THE health record of students and pupils at the Columbia Institution for the Deaf has been a remarkable one. For a period of over thirty years, during which the number of pupils and students has varied from 135 to 180, there have been only two deaths caused by disease. What has insured good health among the pupils of the institution? It would seem that this record may be due to a number of factors, almost all of which may be easily put into operation in any similar educational plant.

The first item of insurance of good health worthy of mention is location. The Columbia Institution for the Deaf is situated on the outskirts of Washington City. It is easily reached on short notice by our physician and by special delivery of necessary medicines. Our grounds, however, approach in extent and varied features a country estate, comprising 103 acres of lawn, farmland and forest. The site combines, therefore, the advantages of opportunity for prompt medical aid with good air and ample room for recreation.

The second point of insurance is our water supply. For many years the city of Washington has filtered most carefully and tested bacteriologically all the water used by the population of the city.

The next insurance item is the milk supply. The small amount of this product purchased by the institution is pasteurized. Practically all that is used, however, is produced upon the farm, which is part of the institution grounds. A herd of tuberculin tested cattle is maintained, milking is done under sanitary conditions, which includes medical inspection of milkers, weekly bacteriological tests of the milk produced, careful sterilization of cans, bottles, and all utensils, the prompt cooling of the milk, and its use within twenty-four hours after production.

Health Habits Fostered

The next general item of insurance may be put down as regularity of habits. In our institution, which is composed of a primary and grammar department for younger pupils and a

preparatory and collegiate department for older boys and girls, a regular program is always in force. The younger children are sent early to bed, are required to clean their teeth properly and regularly, to bathe at regular intervals, to eat at fixed times and to study, play, and work under supervision. Enough teachers and officers are employed to give much personal attention to every pupil. In the higher department also, regular hours of study and recreation are required, lights are turned out at definite times and all absences from recitations are followed up promptly so that medical attention may be given at once in needful cases.

The next point of importance in the insurance of health of our student population is the requirement of physical exercise. Frequent setting up drills are required of the younger pupils. Baseball, basketball and other games are encouraged and even the smallest children play outdoors for a considerable period every day that weather permits. All of the students of the collegiate department, unless excused for some special reason by our physician, are required to take regular exercises throughout the scholastic year. Football, baseball, basketball, tennis, track work, wrestling, and swimming are encouraged in every reasonable way. Two swimming pools are available for the use of students. Everyone must be engaged either in one of the regular sports or in physical exercises under the general control of athletic directors. Good sized athletic fields with a track and tennis courts are available for outdoor exercise during all but the coldest months, and two gymnasiums give opportunity for indoor work throughout the year.

All of these general items of health insurance have no doubt a great influence upon the general physical condition of our students and pupils. It may be of interest for the readers of *THE NATION'S HEALTH* to know of more particular methods by which the students of the Columbia Institution for the Deaf are kept free from illness.

The first of these particular means is a thorough physical examination

upon entrance. Children entering the lower department are given a careful physical examination by our physician, a specialist in children's diseases. This is supported by statements of parents as to diseases already passed through, accidents, etc. The same method is pursued with those admitted to the collegiate department, except that even before admission physical examination blanks are sent to the schools from which students come, and are there filled out by the physician in charge. These blanks require a full statement of height, weight, general and particular physical condition. The examination after admission is also a careful one.

All pupils and students who have not been vaccinated against smallpox and inoculated against typhoid are given prompt treatment upon admission to the institution. Where teeth, throat, ears, nose, or eyes seem to require special attention, students and pupils are sent to specialists for further examination, prescription, and treatment. A permanent record is kept of the health of every student and pupil and in case of any serious disturbance a record of this is made together with the treatment given by the physician.

Physical Index Kept

A weight chart is kept for every student and pupil. The children in the Kendall School are weighed each week by the teachers, while the students of Gallaudet College are required to weigh themselves under supervision of athletic instructors. When an unusual change in weight appears through the chart, the attention of the attending physician is called to it and special diet is prescribed by him in necessary cases.

Each dormitory is supplied with a dispensary containing simple remedies and necessary equipment for the treatment of cuts, burns, and minor ailments. Whenever dangerous looking throats are discovered or eruptions appear, prompt isolation is employed. Rooms for this purpose are reserved in each dormitory.

Special attention is given to the teeth. A dental room is outfitted with modern appliances and is open two af-

Columbia School for the Deaf. (1) Chapel. (2) Young men's gymnasium. (3) College men's dormitory. (4) Kendall School and small boys' dormitory. Good air, ample room for recreation, a régime that is regular without being stereotyped, provide a good health background. Medical aid when needed, but prevention chiefly, constitutes the highly effective health insurance here.

ternoons a week under the charge of a regularly attending dental surgeon. An effort is made to give each student a careful examination and necessary treatment at least once during the scholastic year.

Talks on health, diet, care of teeth, are given to the parents of the younger children from time to time and special courses in physiology and hygiene are required of all students in the collegiate department.

A varied but simple diet is supplied to students and pupils. A quart of fresh milk is allowed to the children of the Kendall School daily, but tea and coffee are not served. From time to time expert advice is sought in

regard to menus, quantities served, and methods of preparation, from authorities outside of the institution.

Serious Illness Unusual

It may be thought that very especial attention must be given to the ears of our deaf pupils. This, however, is not so in most cases. The general condition of the ears of those born deaf is often excellent. Where deafness is caused by spinal meningitis or falls and the auditory nerve is affected there is usually no difficulty in the middle ear.

There are of course some cases where the middle ear shows more or less chronic inflammation. Simple

douches take care of these usually. Only once in a great while is any operative action necessary.

With the health insurance thus briefly outlined serious illness is most unusual among the students and pupils of the Columbia Institution for the Deaf. Nothing that is attempted in this line cannot easily be duplicated elsewhere, except perhaps the liberal provision for room and uncontaminated air. Our chief endeavor, and it seems to have been successful so far, has been to prevent sickness; and with reasonable care such an attempt should meet with success in any residential institution for young people.

Massachusetts Provides for Health in Prisons

BY SANFORD BATES, COMMISSIONER DEPARTMENT OF CORRECTION, BOSTON, MASS.

THE Massachusetts department of correction has general management and administration of the five state penal institutions and certain powers of inspection and recommendation with respect to the twenty-two jails and houses of correction maintained and administered by the counties.

State institutions comprise state prison at Charlestown, for felons (so-called) serving a maximum and minimum sentence of not less than two and one-half years; Massachusetts reformatory at Concord Junction, for younger offenders of ages averaging between 21 and 22 years, sentenced on an indeterminate basis of not more than two and five years; reformatory for women at Framingham, receiving women for all offences and on both the indeterminate and the determinate sentence basis; state farm at Bridgewater, primarily for misdemeanant prisoners of the vagrant type. Included at this institution are separate departments for the criminal insane, for the defective delinquent, for the drug addict, and for the aged and infirm; prison camp and hospital at West Rutland, composed of a tuberculous hospital for prisoners from both state and county institutions and a camp section in which are employed able-bodied prisoners who can be trusted to work in the open air, from both state and county prisons.

The state prison and the reformatory for women are primarily industrial institutions, combining practical instruction in industry with school instruction and physical education. The principal industries at Charlestown are the making of shoes, automobile license tags, aluminum ware, brushes, underwear and clothing; and at Framingham, flags, needle trades and knitting.

The Massachusetts reformatory provides trade instruction in schools devoted to teaching plumbing, tin-smithing, sloyd and printing, and maintains a substantial textile mill and furniture industry. A graded school, military drill, complete hospital regimen and a mark system leading toward parole are outstanding features of this institution.

The state farm and the prison camp and hospital both place emphasis on out-door work as a therapeutic and remedial treatment for men broken down by excess or undue confinement.

In addition to supervision and management of these institutions, the department of correction maintains one of the most complete and scientific bureaus for criminal identification in the country with about one hundred and twenty thousand separate fingerprint and Bertillon records.

The supervision of paroled prisoners from state institutions forms an important part of the work of the department, there being five male and two female agents engaged in this work. The distribution of aid to discharged prisoners is cared for by a male and a female agent. A home department, concerned primarily with the alleviation of unfortunate home conditions and forming a basis of communication between the prisoner and his family, is an important branch of the work.

Other activities of the department include gathering, compilation and distribution of prison and criminal statistics, supervision of prison industries in both state and county institutions and distribution of the products, inspection of county prisons, purchase of certain supplies for joint use of institutions, and a general clearing-house for the public on matters affecting penology and criminology in the state.

The Board of Parole connected with the department has as its function the granting and revoking of all paroles from state institutions. It also sits as an advisory board of pardons to the Governor and council, two members of this board of three being appointed directly by the Governor.

Treat Mental and Bodily Ills

Principles underlying the work of the department of correction and its institutions today proceed upon the modern theory that all efforts along penological lines should be made toward the reformation of the individual and the consequent elimination of criminals from the body politic. It is well to bear in mind that the prisons today are obliged to work with those individuals who represent failures of all other agencies and departments of government, both private and public. Penologists look with favor upon all kinds of community effort to minimize the causes of crime, approve the extension and thorough operation of the probation system, and attempt to put the operation of

their own institutions upon the basis of scientific social work with a view to accomplishing the almost impossible task of reforming those individuals with whom society has failed.

There are those in the world today who sincerely believe in the efficacy of punishment, and claim that the more severe it is the better for society as a whole. There are others equally sincere who claim that society has no right to inflict punishment upon its unfortunate or unprivileged members. Probably no science has progressed so far in the last seventy-five years as has the science of penology. The old doctrines of retribution and punishment as a deterrent are fast losing their advocates.

It is coming to be generally recognized that—first, all the guilty are not caught and punished, and second, that a very real inequality exists in the physical equipment, in mental adequacy, and in environmental and hereditary influences which have a real effect upon criminality. These two ideas are leading people to take the generally adopted view which substitutes individualized remedial treatment of the prisoner for wholesale and indiscriminate punishment of the criminal. The prison today sets itself to the task of eliminating from its population all those persons whose problems can best be handled by other agencies. The insane, the juveniles, and the feeble-minded, but lately considered as criminals, are today diagnosed as sick persons in need of treatment. We would not at this time claim that there are not whole-minded, able-bodied, deliberate criminals who need punishment and from whom society needs to be protected. With these people we shall do our best by means of steady employment, school instruction, religious inspiration, and a logical scientific penal system, to turn them into law-abiding citizens; but our plea to the citizenship of the commonwealth is that before consigning a man to prison the community should see that it has discharged its obligation to see that every boy and girl, man and woman, shall have a healthy body, normal mental equipment, a fair chance to succeed in industry, and an appreciation of the privileges of American citizenship.

We realize that prisons are not the best places in the world. We under-

stand the natural aversion of courts and relatives to have offenders go to prison, and we understand the great possibilities of contamination and evil influences which must inevitably sur-

round an inmate, but we confidently expect the cooperation of all our citizens in our endeavor to so man and equip our penal institutions with competent, interested officials and officers

that they may fulfill the modern function of a reformatory hospital and become less and less the forbidding dungeons which they have been in the past.

Organic Methods of Child Education

Fitting School to Child Allows For Higher Mental Development

BY MARIETTA JOHNSON, EDGEWOOD SCHOOL, GREENWICH, CONN.

THERE is a tendency to measure success in education by the size and cost of buildings, perfection of equipment, and learning of the teaching staff. In industry and education emphasis has been placed upon the thing done rather than upon the doer; the product has become of greater importance than the producer. We do not wish to minimize the value of the building, learning of the teaching staff, equipment, or achievement of the pupils, but we do wish to emphasize the all-round life of the student as he grows in and through these conditions. The question then becomes not what does the child know nor what can he do but what does the knowing do to the child? In other words, we wish to place the emphasis on the human element rather than on the material element.

The school to be successful should make its standard one of meeting the needs of the growing organism of the child at each stage of development, and its success should be measured by its ability to do this. Society and the school owe every child guidance, protection, stimulation, direction, control, and inspiration up to twenty-two or twenty-three years of age when full

physical growth is attained, and this, whether the child is gifted, superior, or inferior. The more limited, the more undeveloped, the more difficult a child is the more he needs the manifestations of the school. The individual needs and growth of the child are superior to the curriculum. The great trouble with adults is an obsession to get a certain something that is within them over to the child. There is little concern with what his feelings, thoughts or desires may be, or with what his actual needs may be.

What Does Child Need?

Many years ago I was teaching the state normal schools of Minnesota. At that time I was very proud of the way in which six-year-old children could be taught to read through four first readers in three months. Without thought of what this work might do to the child I was proud of the results I had obtained. One day my superintendent handed me a book saying, "Unless education takes this direction there is no incentive for a young man to enter the profession." The book was Oppenheim's *Development of the Child*. On reading this book I found to my dismay that

nearly all of those things I had been doing with such pride were, according to Oppenheim, in direct violation of the nervous system of the child and were thus a hindrance to his growth. Thus began my education for the education of the child, and the problem has ever since been constantly before me.

Later, when my own son was old enough to have something in the way of an educational program we moved to Fairhope, Ala., a little town on the eastern shore of Mobile Bay across from Mobile. A school was opened in a little cottage, my home, with my son and a few neighbor children as pupils. No tuition was charged because I was so earnest in my desire to approach education of children from this new point of view that I should have been willing to pay children to come. My whole attitude now became one of seeking to know what the organism of the growing child needed rather than trying to make the child meet any demands of the school.

Education is life. Growth of the educational process must be life-giving—life-giving to the body, life-giving to the mind, life-giving to the spirit. The questions now constantly in my mind were: What are the needs of the body; what are the needs of the mind; what are the needs of the spirit; how may the school meet these needs? No one knows what these needs are, and perhaps no one ever will know, but it remains the supreme duty and privilege to study to know and to try to meet these needs.

This is what our school at Fairhope, Ala., is honestly trying to do. There are a few needs of the body which perhaps all will agree upon. The child should have freedom of action. The children should not be crowded together in a room. The school should substitute tables for desks, and no teacher should be required to have more than twenty children under her care. The order of the development of the nervous sys-

To fit the school to the child is the aim of the Fairhope school. Kindergarten children are here at work in the garden.

Pole vaulting and similar field activities keep the high school boy at Fairhope interested.

tem of the child should not be violated. Therefore, no formal work should be given to children of six or seven years of age. Children are interested in materials and in action and should be allowed to make and use things. Young children need a great deal of creative hand work, singing, dancing, games and play. Self-prompted creative occupations rather than book work should constitute the greater part of the school program for all children. The play instinct of the young child should be given freedom to function in joy.

There are two phases of play, one for exercise, the other for an end. It is often felt that play is work if it is done for an end, but in reality a thing done for an end is play, if the end is the child's. If the child does a thing for an end that is not his own, but one imposed by an adult, then it is work. Play is the child's work. Play is desire for the end and for the activity.

From its small beginnings, the school has grown year by year. The school at Fairhope now occupies ten acres of ground, has nine buildings and an enrollment of over two hundred pupils from kindergarten through high school, and a training school for teachers. It is free to the children of the town and is conducted under public school conditions in the hope that it may through its experiments and demonstrations be of service to the public school system. The school also has a boarding home for non-resident pupils, drawn largely from the North.

Children are grouped according to chronological age. We provide for each group to the best of our knowledge and ability occupations which preserve the health of the body, the intelligence of the mind, and the sincerity of the spirit. The kindergarten child is fluid, unformed, immature. His nervous system is not co-

ordinated and is changing rapidly. Great care is taken to provide an environment that will not repress, inhibit, or over-stimulate him. So no formal work is given. The first thought is, what is the child's interest? Our program for the kindergarten child consists in music, creative hand work, stories, games and free play. Music—rhythms, singing, dancing, games, dramatics—is a vital interest. Stories are used to satisfy the inner desire of the child, not for the sake of language, nor for the sake of re-telling to the teacher. If the child gets from the story imagination, dreams, these cannot be retold. We try to leave the child his dreams.

At the age of eight we teach the children to read and write, but no special attainment or achievement is required for so-called promotion. The child who is constantly marked and graded and measured often develops an inhibiting self-consciousness which may become paralyzing in later life, or he may become wholly externalized.

Children of the same age work and play together even though some of

them do very much less than others. As soon as the children learn to read their stories take the form of stories of geography, history, literature, the teacher supplementing the reading with charts or maps or pictures and making the work as vital and interesting as possible. Later, geography, history and literature stories are dramatized and worked out in the shop, in the sewing room, in the arts and crafts. When in the class room, the group sits around a table working, studying and talking, but a great deal of time is spent out of doors carrying out various school projects, gardening, walking through the woods and hunting out plants, birds and insects, swimming in the bay, hiking and camping and becoming acquainted with the great outdoor world and enjoying life in it. At the close of the day the children are tired after a full, wholesome day of happy play and work, and go home with no lessons assigned and home tasks required. The assigning of tasks is an intrusion upon the child's rights and thus tends to undermine his sincerity and morality. The child is a reacting organism. He reacts to his environment, and should be allowed to react to his home environment without any burden from the school. When home tasks are assigned it often tempts the child to appear to know when he does not know, which is undermining to his sincerity, the only basis for true morality.

As the child grows older the program becomes more complex and definite with a large purpose, but the effort is always made to keep it the child's purpose.

We call our groups "life classes" because we are making an effort to provide an environment in which children may live as wholesome and in-

Junior high school boys off for a hike and camping trip.

telligent and happy lives as possible, and if we can succeed in this children will desire information and instruction, for no one can live an intelligent life without adequate learning. We try to provide for the growing organism of the child, an environment which preserves unselfconsciousness. Selfconsciousness is a sort of fear and fear is a kind of death. Education is life. Therefore, to be educational we must preserve as perfect an unselfconscious expression as possible. Life is a constant awakening, and if some child is slow in his development and does not seem to learn as quickly or attain a skill equal to that of his fellows, that does not make a change of grouping necessary. The teacher makes an effort to give him any personal attention that may seem necessary, or in case a particular child shows unusual ability, this does not mean grouping beyond his years. The prolonging of childhood is the hope of the race. We make an effort to give the child more work rather than place him with older children. He should have intelligent work which challenges his powers, but this should not subject him to the strain which grouping with older children would necessitate. Often the social and sex consciousness of the younger children is stimulated by grouping with older children. The child needs to work and play with his own group.

At the age of fourteen, children in the Fairhope school are entered in high school. Life itself indicates the period of childhood to be up to about fourteen, when youth begins. Youth needs the companionship of youth, and that, even though a certain youth may not have had all the work of the preceding years. The adolescent period, from fourteen to eighteen, is one of strong, definite instruction. The youth can do more work, perhaps, than at any other time, but should not work under strain.

Working for grades, marks, promotions to please the teacher or to escape punishment is an insincere experience which may prevent true moral conceptions. All conceptions grow from experience rather than through instruction. Promotion is an externality in the educational process, and, instituted as a convenience, tends to fix the curriculum and transcend the individual needs of the youth. It is an outward reward for learning, while the real reward for learning consists in the knowing. External rewards make for arrogance and insincerity. We give our high school boys and girls four years of serious, earnest work in science, mathematics, history, literature, languages, continuing the manual training, arts and crafts, sewing, cooking, gardening, and athletics. The motor minded children are given the same opportunity for development and self-prompted creative activity that children of a different mental type are given.

Education Is Life Itself

We believe in co-education, and, while occasionally the attraction between boys and girls interferes somewhat with thorough academic work, we believe that these attractions are educational. The adolescent period has not been understood, and its problems have not been met. There is a wide field for investigation and experiment in this period of growth. The young people of this period are more or less uncertain and are full of surprises for both teacher and parent. Many times the young person who has been tractable as a child is quite irritable as a youth, and sometimes the child who has been most difficult becomes quite amenable to direction at this period. Much of this is due to growth itself and adults must have patience and try to meet this with sympathy and understanding.

We try to get our high school boys

and girls to cooperate with us in not giving or accepting an invitation for any social affair on Monday, Tuesday, Wednesday and Thursday nights, and then we cooperate with them by not assigning any tasks on Friday nights, leaving them free until Monday morning and permitting them to come to school with clear consciences and light hearts, even at the risk of empty heads. We are not afraid the children in high school will not "cover the ground."

Our whole effort is to meet the needs of the growing organism at this period of development. If this is intelligently done we believe that every normal youth will develop power and skill and information during the period from fourteen to eighteen which will enable him to meet the requirements which the colleges set up. We believe that the colleges all over the country would be glad to abolish entrance requirements if they were assured that the young people of the country had had this developing process during the preparatory years, and we might add that the preparatory schools would be better able to give the young people the right process for growth if the colleges did remove their requirements and frankly accept these young people because of their maturity and need for the college process.

Education is life—a larger, better life. This is the immediate end of the educational process. The school should not be a preparation for life, but should be life itself. In the measure that the primary school provides activities and occupations which meet the needs of the growing child, it is educational. In the measure that the high school provides activities and occupations for the youth which secure this human development in the youth, it is educational. In the measure that the college meets the physical, mental, and spiritual needs of these young people, it is educational. In the measure that an institution meets the needs of the growing organism at every stage of the development of the child, it is educational.

Why do we force the young to spend their childhood in preparation for adult life? Childhood is its own excuse for being. The child must live in the present moment. He must live as wholesome a childhood as it is possible for us to give him. As he grows older, his span of interest increases, and naturally he will look into the future, but this we should not force upon him. The present is too precious to destroy by the intrusion of future ends.

If teachers could be relieved from

An English country dance.

the supervisory system, from the pressure of curriculum and the "rate system" of those in authority, if teachers could be trusted and helped to live frankly with the children, giving them as beautiful and complete a present as it is possible to provide, the profes-

sion would attract to itself many superior minds that are now being drawn off into other professions. The work of the teacher would be more creative, and the reward would be confidence instead of fear, joy instead of despair, success instead of fail-

ure, as is so frequently the case.

If we sincerely study the needs of the growing child and make an earnest effort to meet those needs of the growing organism at each stage of its development, then we can safely trust results to life itself.

A Nursery School Where Children Learn to Live

THE fault with our educational system has been that children have been made to conform to a set formula; that they have been taken and planted in a grownup environment; that they have been surrounded with protection to such an extent that free development of their own powers of thinking has been greatly deterred.

But the error is not wholly that of the school. In the home the child is too often helped by wellmeaning adults. If he falls down, instead of being allowed to use his own ingenuity—to exercise his own muscles in rising, a too willing older person picks him up and lavishes on him uncalled for sympathy. If the mechanism of some toy balks and the child gives way to spontaneous crying or unintelligent banging, some one hastens to show him the right way. He learns then by imitation, from an outside source, not through his own effort at thought and experiment.

The solicitude of grownups at home and school greatly handicaps a child. This handicap is further intensified in the upper grades, in high school,

and even in universities where too-willing instructors, learned in the knowledge of the pioneers of their field, facilely spread before the student the result of others' thought. The individual orders his life by accumulated knowledge, custom, habit. Mental flabbiness is seen in government, in business, in social relations. Tragedies are caused not so much by external circumstances, as one likes to imagine, but by inability thoughtfully to meet crises. The history of crime, of suicide, of tragedy lies in this.

Thus, the establishment of a Nursery Experiment School for children from eighteen months to three years in New York City by the Bureau of Education Experiments is a step in the direction of developing an intelligent healthy citizenry.

Fortunate are the children in this school. Not only is their regime carefully worked out as to play and social contact, but their physical care, food and sleep, is a matter of detailed attention and daily study. Each child has a chart on which the teachers, who also take care of the children, note the physical and social characteristics of the days—these being written up in a weekly summary. Shortly after entrance each child is given a thorough physical examination by the physician of the Bureau staff and recommendations are made to parents and to the nursery.

The physical program of the nursery includes taking stripped weights the first day of each week and measurements once a month. Stress is laid on bodily control, on teaching the child to feed and dress himself, on the use of play apparatus, and the development of social contact.

In every phase of the school's activity the children are encouraged to use their own initiative to aid in dressing themselves, to feed themselves, to

climb stairs, to adjust their wants to those of their playmates. Harriet M. Johnson of the Bureau says:

We conceive our problem to be building up an environment and developing a procedure which will not only give children an opportunity for the full exercise of their physical powers and for real adventure, but which will also look toward the growth of these impulses into directed and organized activities. Beyond this we are opening up to them the world of social contacts and social relationships, and it must be remembered that this is the feature of our experiment most needing careful consideration. Taking children under three from their homes and placing them in a group of their peers demands from them fundamental adjustments. Whether or not those adjustments are wholesome and contribute to the health of their emotional life depends in part at least upon the way they are introduced into the activities of the group. We believe that at first children must be protected from too close social contacts, that their individual interests must be allowed full scope, and that little by little their participation in activities that are common to all the children will integrate them with the least possible amount of strain and friction.

To enable its 400 medical students to maintain a high health standard, Northwestern University is inaugurating a plan of constant supervision. The regime will enable students to study, work and live better.

In the Nursery Experiment School the young child is given opportunity for testing his own powers. Climbing constitutes for the two year old one of life's great adventures.

A board, nails, and a hammer are giving Jimmie a lesson in sustained interest and fine muscular coordination.

Nursing Organization As Developed in Toronto

**Maintains Harmonious Working Relationships
And Equitable Distribution of Service**

BY CHARLES J. HASTINGS, M.D., MEDICAL OFFICER OF HEALTH, TORONTO, ONTARIO.

TORONTO appointed its first "City Nurse," a tuberculosis nurse, in 1907 but did not begin to develop the service until 1911, the régime of the present Health Officer having begun late in 1910. It is possible to trace a few unchanging policies throughout the development of the division of public health nursing, but the routine duties of the nurses have been subject to more or less constant change.

The director of the public health nursing, Miss Eunice H. Dyke, R.N., has been responsible to the medical officer of health rather than to medical specialists, teachers, or social workers. Every possible contact has been established with the homes in order to bring the resources of the community to the homes, and cooperation has been established with public and private agencies with that end in view. Without confining their efforts to selected age groups or diseases, the public health nurses are busy removing, or helping others to remove obstacles to the health of individuals.

The following outline of the organization of the Division on November 1, 1922, includes only those details which determine or explain the policies of the division at that date.

* * * * *

Toronto has a population of 530,000 and an area of thirty-two square miles. For the administration of medical, dental and nursing divisions, the department of public health has

The nurse as the pivot of public health service is well exemplified in Toronto where from center to periphery of departmental activities nursing contacts are made the basis of correlating relationships.

Full reciprocity is maintained between the Department of Public Health Nursing and other community agencies, and no exigency of individual service is allowed to endanger future cooperation; nor is one service permitted overdevelopment at the expense of another.

The district superintendents, affiliating through the Director of the Division, afford a highly responsive medium through which the Medical Officer of Health finds easy expression for the general policies of the health department.

divided the city into eight districts with headquarters in the city hall. Six of the eight districts have their offices in police stations, and two in rooms rented from social agencies.

A medical officer is responsible through the deputy officer of health, who is director of medical service, for the health of each district. These district physicians have completed courses leading to the Diploma of

Public Health (D.P.H.) and are full time officers. Their duties are limited to the preventive aspects of public health work, treatment of the sick poor being provided through cooperation with the private physicians and the indoor and outdoor departments of the hospitals.

A director of dental services and thirty-five dentists giving half-time service conduct dental surveys in the schools in addition to twenty-six operative clinics in schools and four in out-patient departments of hospitals. The policy of the department is to urge parents to send their children to the family dentists, but if this is not possible, the public health nurses make appointments for the school clinics. The nurses make financial investigations for the hospital clinics when requested to do so by the dentists.

The public health nursing of each district is in charge of a District Superintendent of Nurses who is responsible to the Director of the Division of Public Health Nursing. The Director of the Division is responsible to the Medical Officer of Health.

Assignment of Staff

(A) Central office at city hall. The personnel consists of: Director of Division, 1; Assistant Director, with central office duties, 1; Special Supervisors, 5; Assistants to Special Supervisors, 2; (Special Supervision covers (1); prenatal, infant, and pre-school

hygiene with assistant for maternity homes and boarding homes for babies; (2) school services; (3) mental hygiene—with assistant; (4) venereal disease; and (5) tuberculosis and hospital extension service. Hospital extension service, 12; clerk in hospital, 1; clerks in central office, 2.

(B) Assignments to the eight district offices are indicated in the chart.

The volunteer clinic assistants have an independent organization with a superintendent and four captains. These officers are responsible to the supervisor of infant welfare nursing for the regularity and standards of work. A volunteer who is absent from her clinic without good reason is eliminated by her organization.

The other divisions of the depart-

ment are the Neighborhood Workers' Association secretary in the nurse's district office. The relationship of the division of public health nursing to the N. W. A. will be discussed later.

Duties of Field Staff

The average population assigned to each district superintendent of nurses is 66,250, and the average staff of nurses is about ten. Constant emphasis is placed upon the educational aspect of work in homes, schools, and clinics and the division of records and the special supervisors help the superintendent to analyze the results of her work. The department has endeavored to secure for her every possible avenue of approach to the homes with the exception of bedside nursing. In addition to miscellaneous opportunities of reaching her people, the following may be listed:

Reports of infant births and deaths received daily.

Health service in all public and separate schools.

Child welfare clinics.

Prenatal clinics.

Health services in day nurseries and children's institutions.

Health supervision of maternity homes and boarding homes for babies.

Reports of absentee civic employees.

Reports of communicable disease.

Calls from social agencies.

Calls from private physicians.

Names of all non-paying patients admitted to hospital wards.

Special cases referred from wards and out-patient departments by the nurses of the hospital extension service.

The district superintendent assigns a definite section of her district to each nurse. With a few exceptions, this small district includes one or two schools, and a child welfare clinic if the district needs one. A few districts include prenatal clinics, day nurseries, and maternity homes, and many include boarding homes for babies. School children or clinic mothers living outside the district are referred to the nurse responsible for the neighboring district if home visiting is required. Conference between the nurses in the district office makes this team play possible.

Each nurse takes advantage of all the avenues of approach listed above to become acquainted with the families of her district. In the school, the clinic, and the home, she teaches hygiene and brings to those who are already in need of treatment, the best available medical and social resources. The private physicians and the social agencies already interested are never ignored or discredited. The "city

	Runnymede	Parkdale	Hillcrest	Yorkville	University	Moss Park	Broadview	Scarboro
Superintendent	1	1	1	1	1	1	1	1
Clerk	1	1	1	1	1	1	1	1

Dental Assistants	4	3	3	4	4	5	4	2
Volunteer Clinic Assistants	10	10	10	10	10	10	10	10
Cook and Cleaner	1	1	1	1	1	1	1	1

(C) The total personnel and assignments of the Division of Public Health Nursing are as follows: public health nurses, 112; clerks, 11; dental assistants, 29; volunteer clinic assistants, 85; student nurses are variable in number.

Appointments.—All appointments are made by the medical officer of health and confirmed by the city council. Appointments are based upon the recommendations of the director of the division.

Qualifications of Staff

(A) *Nurses.*—The public health nurses are graduates of recognized training schools for nurses and for the past three years an additional preparation of one year in a University Department of Public Health Nursing or Social Service has been required.

(B) *Undergraduate students.*—Arrangements have been made with the training schools of the city to send six groups of seventeen senior student nurses for two months of unbroken field work. The estimated total of one hundred and two will be exceeded this year.

(C) *Graduate students.*—The department of public health nursing of the University of Toronto depends upon the municipal department for a large part of the practical experience required by their students. Twenty-four students have been enrolled by the university this year.

(D) *Dental assistants.*—Special training has not yet been required for the assistants in school dental clinics, but the public health nurse assigned to the school is responsible through the district superintendent, to the supervisor of school nursing for the service given.

(E) *Volunteer Clinic assistants.*—ment of Public Health work in close cooperation with the nursing services, two divisions assuming special work upon which the nursing services depend.

The division of records organizes and directs all record keeping for the department. An analysis of the nurses' time and special studies of results, which help to guide the supervisors in their policies, are among its many activities for the division of public health nursing.

The division of accounting secures the supplies requisitioned by the district superintendents and special supervisors and gives other kindred services.

Other divisions with which close cooperation is maintained are: Division of Laboratories; Division of Communicable Diseases; Division of Isolation Hospitals; Division of Housing and Industrial Hygiene; Division of Sanitation; and Division of Food Inspection.

In 1921, a welfare branch of the department of public health was established with a director, five trained social workers, and three clerks.

The primary function of the welfare branch is to supervise the city's grants in aid to private charitable institutions, most of which are on a per capita service basis. The phase of this work that touches that of the nurses most directly is the family case work to prevent people becoming or remaining public charges, either in or out of institutions, and to make such public assistance as effective as possible.

Social cases involving field work that appear to be the responsibility of public rather than private philanthropy are referred to the Welfare Branch directly or through the

nurse" remains in touch with situations where health is threatened, regardless of other agencies interested, but she does not risk future cooperation with a physician or social agency by an aggressive policy designed to secure results in an immediate case.

Each field nurse reports at 8:45 to a school where a varied health service is given, the aims of which are three—the control of communicable diseases, correction of defects, and health education.

The medical officer is present at a pre-arranged time for conference with the parents and for complete physical examinations.

Constant watchfulness is required to prevent a full development of the health services in the schools at the expense of other equally valuable but less easily developed opportunities. A definite time-table can be arranged for the medical officer, since his routine duties in the schools are limited to complete physical examinations, appointments for which have been made by the nurse. The nurse's time-table, however, must be elastic. The number of re-admissions of absentees varies with the size of the school, the day of the week, the character of the population, and the cooperation of the teachers. Classroom inspections and health talks vary also in the different schools. The time spent in conference with the teaching staff is a matter which must be left to the judgment of the individual nurse. The analysis of time and of results prepared by the division of records is used by the district superintendents to emphasize the need for purposeful arrangement of time.

The miscellaneous nature of the nurses' duties and the team play involved with other individuals and organizations could not have been developed or controlled without the opportunity for direction offered by the noon hour in the district offices. The nurses report to the district superintendent upon completion of the morning's work. The plan of organization makes it compulsory for the nurses to lunch in the district offices, but the lunch hour, which is conducted on a cooperative basis, has become a happy feature of the organization and is largely responsible for a district *esprit de corps*.

At a definite hour new assignments and written confirmation of telephone messages are received by motor delivery from the central office. The medical officer receives assignments on the same delivery. Before or after lunch each nurse fills in her time sheet for the past twenty-four hours,

makes entries on case histories, prepares special reports for cooperating agencies, telephones physicians and others interested in her families, and joins in conferences arranged by the medical officer or special supervisors.

The afternoon may be devoted to home visiting, to a weekly child welfare clinic, or to assisting the medical officer with complete physical examinations in the schools. With frequent variations due to the nature of her work, the nurse leaves for home at 4:30 p. m.

Cooperating Agencies

It is impossible to understand the part played by the public health nurse in the "welfare game" of the city without understanding the part played by two other organizations, the Victorian Order of Nurses, and a federation of organizations known as the Neighborhood Workers' Association.

The Victorian Order of Nurses in Toronto employs forty nurses to do bedside nursing. In their professional organizations the nurses of the Order are known as public health nurses, but by common usage in the city, that title is limited to the staff of the department of public health. The nurses of the order are all graduates of recognized training schools and the standard of an additional year of post-graduate training has been set recently. The opportunity to teach health in the homes of the patients is receiving increasing emphasis. The fee charged varies with the income, except in the case of the Metropolitan Life Insurance policy holders, the deficit being met by the Federation for Community Service. Owing to the existence of the Victorian Order, the municipality has not attempted to assume responsibility for bedside nursing, but in conference with the nurses of the Order the public health nurses retain many cases requiring temporary service, or cases complicated by actual communicable disease. In various ways the two organizations are cooperating to deal with their common task.

The Neighborhood Workers' Association constitutes a unit of the Federation for Community Service and coordinates the activities of 187 agencies giving some form of social service in the homes of the city. Seventeen secretaries, equipped to do social case work, have been appointed to develop effective team play among these organizations. The various agencies included in the membership of the Neighborhood Workers' Association cover the entire field of pres-

ent day social effort and are becoming steadily more efficient. When no agency can be found to deal with a case the secretary herself assumes the responsibility. In order to simplify cooperation, the Neighborhood Workers' Association has adopted the district boundaries of the Department of Public Health and has encouraged other city-wide agencies in the federation to do so also. Ten secretaries of the Neighborhood Workers' Association share the offices of the district superintendents of public health nurses—as guests of the Police Department in six offices, and as tenants of social agencies in two. They join the nurses at the luncheon hour and other welfare workers of the district, including physicians, visiting nurses, social case workers, teachers, and clergymen, are occasional guests of the group.

As a result of this close cooperation between the two organizations, it is becoming possible for the public health nurses to concentrate upon those aspects of health work which require their special training. Before this personal contact was established between the field staffs of the two organizations, cooperation was so difficult that it was not always attempted.

Hospital Extension Service

One source of information regarding the health problems of a district which is invaluable to the District Superintendent of Nurses is the Hospital Extension Service. The nurses attached to this service constitute a distinct unit within the division of public health nursing. Their organization and duties cannot be described briefly.

Toronto has one municipal hospital—the Isolation Hospital. The remainder are conducted under a provincial Hospitals Act which provides for a per capita grant from the municipality responsible for the patient. Toronto's per capita allowance to the hospitals is \$1.50 per day. This city pays also for out-patient department service at the rate of \$0.32 per visit. The amount paid to the hospitals in 1921 was \$692,203 for in-patient service, and \$55,776 for out-patient service.

The city relief officer decides from his office upon the eligibility of each patient for free treatment in hospital wards. The admitting officer in each hospital makes the decision for out-patient service.

From the city relief office in the city hall, the patient or his friends are sent to the city hall office of the public health nurses, where the "city or-

der" is granted, ambulance arranged for if necessary, and the need for home visiting detected in the more obvious cases. The district office is notified by telephone if immediate advice or help is needed in the home.

Twelve public health nurses are attached to the various hospitals to make a closer contact with the city's patients and to secure cooperation from outside medical and social agencies in dealing with individual or family problems. These twelve nurses are in close touch with both in-patient and out-patient departments of all public hospitals, with the exception of the largest, which had already organized its own social service department at the time the department of public health began to develop its hospital extension service. Responsibility, however, for follow-up work from the chest clinic of this hospital and for tuberculosis patients on the wards is assumed by the public health nurses and close cooperation exists with the social workers in other clinics. The public hospitals to which Toronto sends patients are:

General hospitals: in-patient, 1; in-patient and out-patient departments, 4.

Women's hospitals: In-patient and out-patient departments, 2.

Children's hospital: in-patient and out-patient departments, 1.

Tuberculosis hospitals: Adult, 5; children, 1.

Preventorium, 1; isolation hospital, 1; convalescent hospital, 1; tuberculosis dispensary, (no city grant), 1; hospital for incurables, 1; and hospital for epileptics, 1.

The clinics provided by the hospitals are: chest, 6; circumcision, 1; dentistry, 4; dermatology, 5; ear, nose, and throat, 6; eye, 5; gastrointestinal diseases, 1; genito-urinary diseases, 2; gonorrhea, 6; gynecology, 5; heart, 3; homeopathy, 1; medicine, (general), 6; neurology, 3; nephritis, 1; nutrition, 1; obstetrics, 5; orthopedic conditions, 2; psychiatry, 1; surgery, (general), 6; and syphilis, 6.

Obviously, it is impossible for twelve nurses to attempt the social treatment and health teaching required by the homes of the individuals admitted to these hospitals and clinics, and we do not expect them to ignore the many and select the few for the purpose of demonstration or for any other purpose. Their task is to provide a link between the hospitals and the outside agencies, who are prepared to give the treatment needed. The task is not a simple one but we believe it can be handled with satisfactory results in Toronto on account

of the district organization and its close relationship to the Neighborhood Workers' Association. The public health nurses assigned to this particular team play should be selected for executive qualities not possessed by the average individual. They should be prepared to do intensive social case work when, as occasionally happens, it is unwise to enlist the services of another organization. They must be able, also to interpret the social aspects of the case and the plans of outside agencies to the medical and nursing staffs of the hospitals. The public health nurse assigned to this branch of the service must have been a member of the general staff and have become well acquainted with the organizations included in the Neighborhood Workers' Association if she is to refer cases for nursing or social treatment in such a way that effective treatment will result.

The Hospital Extension Service in grappling with a problem which is common to every large city on the continent, has adopted a principle or method of working probably nowhere else attempted. There are difficulties still to be overcome by both the Extension Service and by the social agencies represented in the Neighborhood Workers' Association but already a very significant contribution has been made to the problem of meeting the social needs of sick persons and their families from an entirely new angle.

Venereal Disease Service

The general plan of hospital extension service has been modified to meet special conditions, in some instances for short periods and in one instance as a permanent policy.

The medical social service work in connection with syphilis and gonorrhea clinics is attempted by the nurses of the hospital extension service. Selected cases are referred to our own district staff or to suitable social agencies, and the plans of the clinicians are reported to responsible social agencies who have referred cases for diagnosis and treatment.

The necessity for secrecy if we are to retain the confidence of the public as well as of the private physician who refers cases to clinics makes it impossible to enlist the help of outside agencies to the same extent as in other diseases.

It has been found that the director of the division and the district superintendents require the assistance of nurses who can concentrate upon certain aspects of the work of the division. At present five supervisors

are required. These nurses keep in touch with the changing policies and personnel of cooperating agencies, the majority of whom concentrate their attention upon age groups or selected medical and social problems. The supervisors bring the experience of these specialists to the division and help the director and superintendents to formulate the policies governing team play, in addition to helping with the supervision of the routine work of the public health nurses in the field.

The policy of each special supervisor is determined by factors peculiar to the problem with which she deals, by local history and personalities as well as by her own personality, with the result that no two supervisors adopt the same methods. Their duties change as the city-wide situation develops.

The following summaries indicate the relationship of the supervisors to other organizations and to our own Department.

Child Hygiene Section

The Supervisor of prenatal, infant and pre-school Child Hygiene, represents division on Child Welfare Council of Toronto and Canadian National Council of Child Welfare; gives eight lectures a year in connection with department of public health nursing, University of Toronto, and directs field work given to selected students; reports to director of the division of child hygiene, who is also chief of medical staff at the Hospital for Sick Children, and professor of pediatrics at the University of Toronto; is responsible for cooperation with Victorian Order of Nurses in regard to prenatal and infant hygiene.

With the help of an assistant who supervises licensed maternity homes and boarding homes for babies, the supervision of prenatal, infant and pre-school child hygiene endeavors to limit the department's responsibility in child placing to the health supervision of boarding homes. This has involved a close relationship to a very complex situation amongst child placing agencies.

She holds weekly conferences with the director of child welfare clinic volunteers and plans with her the distribution of volunteers and the type of service necessary to meet the growing needs of clinic work, and advises as to location and equipment of child welfare and prenatal clinics and, together with the district superintendents, supervises these clinics.

She organizes special activities, *e. g.* a summer clinic at Toronto Island.

With the help of the division of rec-

ords, the supervisor analyzes findings in child hygiene work and in a variety of ways, helps the district superintendents to direct their staffs along the lines most productive of results; arranges lectures or conferences for the district staffs when changing theories or methods of treatment make it necessary; and prepares department literature on prenatal and infant hygiene, with the help of specialists, under the direction of the deputy medical officer of health.

School Nursing Section

The supervisor of school nursing represents the division on home and school council of Toronto, Ontario Educational Association, and American School Hygiene Association; gives seven lectures on school nursing to students enrolled with the department of public health nursing, University of Toronto, and directs field work given to selected students; organizes special course of twenty-four lectures for department of social service, University of Toronto. The students enrolled in this course are the senior pupil nurses from nine hospital training schools.

She confers with the deputy officer of health and director of school dental services regarding policies and routine of nurses' duties in connection with the schools and home visits to school children; confers with the chief inspectors of public and separate schools with reference to cooperation with teaching staffs, selection of pupils for special classes, and similar matters; represents division on committees appointed to deal with special problems such as milk distribution and the handling of material relief in the schools; organizes the staff, through the district superintendents, to deal with special duties such as health leagues, milk distribution, weight and measurement survey, and selection of children for special classes; recommends, to the Director of the Division, the appointment of Dental Assistants and organizes their service in the schools, placing them under the immediate supervision of the nurses in the schools and the District Superintendents; selects posters and literature for the use of the staff; assists division of records in the preparation of an analysis of service sent monthly to school principals; analyzes results with the help of the division of records and helps the district superintendents to develop methods most productive of results, to eliminate non-essentials and to avoid spending too large a proportion of available time within the school walls; and assists

district superintendents in maintaining an efficient and uniform school nursing service by supervising that service in the schools.

The supervisor of venereal disease service is the representative of the nursing division on the Toronto Social Hygiene Council, and she assists in the enforcement of the venereal diseases prevention act. The duties attendant upon this part of the work include: Daily attendance at the Women's court for the purpose of interviewing persons who may be brought under the Act; visiting the jail and municipal farms for the purpose of interviewing persons detained there under authority of the Act; advising and conferring with physicians and public health nurses, police, Provincial Board of Health, social agencies, and private individuals, regarding persons to be brought under the Act.

The supervisor of this service handles special cases which are not known to the district, or where it may be unwise to give them to district, *e. g.* contacts of persons whose death has been registered as due to syphilis or its sequelae; attends women's court to assist magistrate in dealing with cases requiring cooperation of outside agencies; assists supervisor of hospital extension service in organization of syphilis and gonorrhea clinics; and organizes monthly conferences with five nurses of Hospital Extension Service, conferences which they in turn conduct in the district offices.

The supervisor of mental hygiene service and assistant—arrange for surveys to be made in the schools by the psychiatrist; assist him and his secretary in conducting these and in the re-examination of many pupils seen previous year; accompany the psychiatrist on his visits to the auxiliary classes and by frequent visits between times keep in touch with their teachers regarding progress of the pupils and problems arising from their mental condition; maintain co-operation for the department with the psychiatric clinic of the Toronto General Hospital and the psychiatrist of the Juvenile Court.

They arrange for admission of emergency cases to the Hospital for Insane and for application for admissions to the other various Ontario hospitals and special institutions for the handicapped, and initiate the follow-up work among the children who have been in the auxiliary classes and are now out of school either at home or at work.

It has been found possible to place the general supervision of the tuber-

culosis work of the division in the hands of the supervisor of hospital extension service. This supervisor is already closely identified with the sanitariums and with the chest clinics, all of which—with one exception—are part of the hospital out-patient departments. The district superintendents require comparatively little help in directing the tuberculosis work of their staffs in either schools or homes. The supervisor of hospital extension service has certain special duties, however, which deal with the control of tuberculosis and which cannot be left to the district superintendents.

She represents the division with, Canadian Association for Prevention of Tuberculosis and with two social agencies identified with tuberculosis clinics; enforces physicians' notification of tuberculosis; and with the help of the division of records, forwards prompt reports to the districts of sputum reports, admissions to sanitarium, and deaths.

Regular Conferences Held

The district superintendents meet at least every two weeks in a district office to formulate recommendations as to policies and to confer upon details of administration. The director of the division and her assistant are usually present at these conferences. The supervisors meet formally or informally in the Central Office when necessary. A joint conference of superintendents and supervisors is held every two weeks with the director of the division or her assistant presiding. A representative from the division of records and statistics is always present. The deputy officer of health is notified of all meetings and attends occasionally. Topics for discussion are presented from the districts and dealt with by the supervisors or referred to other divisions of the department and other organizations for advice. The supervisors submit proposed action for discussion, and criticize district methods and results.

Occasional meetings of the entire staff of the division are held in the city hall, when questions of department policy can best be presented in that way, or when representatives of other city organizations or distinguished visitors from other cities have subjects to present which justify this expenditure of staff time. The director of the division presides at all staff meetings.

On these occasions, the chairman of the council which is elected by the staff may call a meeting to deal with the professional or social interests of the staff.

Dr. Frankel, Chairman of N. H. C.

THE National Health Council held its annual meeting on January 6 in the New York offices of the Council. The principal item of business was the election of officers for the year 1923.

Dr. Lee K. Frankel, long a prominent figure in health work in America, was elected chairman to succeed Dr. Livingston Farrand. Dr. Frankwood Williams, the medical director of the National Committee for Mental Hygiene, was elected vice-chairman to succeed Dr. Frankel. Dr. S. J. Crumbine, secretary of the Kansas State Board of Health, was elected to succeed himself as Secretary of the Coun-

significant statement concerning the Council:

Many factors have contributed to the great advance made in public health during the last half century. Of these, increase in scientific knowledge must be given the first place, but the public interest which has made that knowledge effective has also played an indispensable role. This has resulted in the formation of many voluntary organizations all seeking the betterment of health and vitality but operating, as a rule, along specialized and independent lines. The National Health Council has been brought about to coordinate and unify these efforts. Its organization and development is one of the most important steps taken in the field of public health in recent years.

Dr. Lee K. Frankel, long a prominent health worker, now heads National Health Council.

cil, and Dr. William F. Snow, general director of the American Social Hygiene Association, was elected to succeed himself as treasurer.

All the members of the council, as follows, were represented: American Public Health Association, American Red Cross, American Social Hygiene Association, American Society for the Control of Cancer, Conference of State and Provincial Health Authorities of North America, Council on Health and Public Instruction of the American Medical Association, National Child Health Council, National Committee for Mental Hygiene, National Organization for Public Health Nursing, National Tuberculosis Association, and the United States Public Health Service.

Dr. Farrand, the retiring chairman of the Council, issued the following

Private Physicians Should Give Periodic Tests

We are glad to give space to the statement below by Dr. Hermann Biggs since it expresses an admirably sane and constructive attitude relative to an important matter of personal hygiene.

At the annual conference of Health Officers and Public Health Nurses of New York State held at Saratoga Springs last June, I referred to the importance of periodic physical examinations, which I have long advocated as a means for the preservation of health and the prevention of diseases through early recognition and correction of defects and abnormal conditions. Comments which have since appeared in a number of newspapers indicate that serious misconception exists in some minds as to the purport of my remarks. The impression seems to have arisen that I favor an official scheme of compulsory physical examinations, to be conducted by health officers or other physicians employed by the public authorities, with the implication that every man, woman and child should be required to submit to such a periodical inquest into his or her physical condition.

It does not seem really necessary to explain that I agree heartily with the critics of any such proposal, and that I never have and do not advocate any kind of compulsory state medical inspection of the individual citizen, except as such inspection is now carried on practically everywhere in our public schools and in charitable and penal institutions. A prying inquest by public authority into the physical condition of the adult citizen would be utterly repugnant to American ideas of individual rights, and of the proper sphere of government. The worst enemy of periodic medical examinations could choose no better means of making his opposition effective than to advocate such a fantastic plan as seems to have been read into my address at Saratoga.

So much having been made clear, I ask space to repeat my conviction that

nothing is more important for the citizen who cares to keep well than that he should go of his own free will to his own physician and demand thorough examination at reasonable intervals, with the application of all the resources of modern scientific medical knowledge. This means not merely a hasty examination of the heart and lungs with the stethoscope, but a complete medical survey, including various special tests of the blood and excretions, examination of the eyesight and hearing, as well as of the nose and throat, and often accompanied by an x-ray of the chest or other parts of the body. Adequate examination also means taking into account mental as well as physical factors, and basing conclusions on a full knowledge of living and working conditions, income habits, recreations, and the pertinent facts of family and personal history.

It must be obvious that such examination and advice based on it can be properly made and given only under the conditions of freedom and intimacy which are implied in the relation of the individual to his family physician. For the state to attempt thus to examine its citizens would be not only intolerable but futile, since the utmost degree of confidence and cooperation on the part of the patient is required if anything is to be accomplished. The best trained modern physicians are equipped to examine and advise their clients how to keep well, and rightly expect to be consulted for this purpose and not merely to attempt the cure of an established disease. Perhaps it is not true that the Chinese pay their doctors only to keep them well, but if this popular legend is not based on fact it was at least well invented, for it expresses the essence of the coming system and practice of civilized society. As was said recently in one of our radio health talks "The human body is the only machine for which there are no spare parts." We must learn rightly to use and carefully to safeguard those which we have. And we can best do this by picking out a competent medical adviser, consulting him frequently, believing what he says, and following his counsel.

A rural health survey on which proposed legislation will be based will be made by a committee consisting of two representatives each from the New York State Farm Bureau Federation, State Grange, Dairymen's League, New York State Home Bureau Federation, and one each from other states organizations doing health work. Existing health agencies will be investigated by a special committee consisting of S. L. Strivings, N. Y. State Farm Bureau Federation, Prof. Dwight Sanderson, State College of Agriculture, Ithaca; Dr. M. Nicoll, Jr., deputy state health commissioner; George J. Nelbach, State Charities Aid Association, and Mrs. Henry Burden, State Home Bureau Federation. Mr. Sanderson is chairman.

Health Agencies in the District of Columbia*

A Preliminary Study Looking Toward Complete Coordination

By WALTER CLARKE, ADMINISTRATIVE SECRETARY, NATIONAL HEALTH COUNCIL, NEW YORK CITY.

THE situation in the District of Columbia is different from that existing in any state, yet in these studies it seems fitting to consider the District of Columbia on the same basis as a state. One has the precedent of the Conference of State and Provincial Health Authorities for this classification, as that body considers the District of Columbia, for the purposes of the conference, as equal to a state. On the other hand, it must be pointed out that the District of Columbia is practically the city of Washington with a narrow fringe of suburban and rural country about it. The problems of the District are practically those of a city and the developments which have taken place in the direction of coordination are similar to those which have taken place in a number of cities.

Exceptional conditions exist in the District of Columbia. Among these conditions the following may be mentioned:

(1) All District affairs are eventually in the hands of Congress and legislation and appropriations for the District are passed as acts of Congress. This condition operates to the disadvantage, I believe, of the health work in the District of Columbia on account of the great difficulty of moving Congress upon the comparatively unimportant affairs of the District. Legislation is very difficult to secure and I am given to understand that appropriations for the District health work have been inadequate.

(2) A number of national voluntary organizations engaged wholly or partly in health activities make their headquarters in Washington, among which may be mentioned the American Red Cross, the National Health Council, the American Child Hygiene Association, the National Research Council, and the National Child Health Council. Furthermore, Washington is the headquarters of the United States Public Health Service, of the Bureau of Education, and of the Children's Bureau. The presence of these national official and voluntary agencies in Washington should be a source of strength in the development of health activities in the District.**

(3) Washington has a disproportionate temporary population of distinguished American and foreign men and women. Representatives of foreign countries, members of Congress, and persons engaged in government work outside of civil service, make up a considerable part of the population of Washington. This portion of the population exerts a considerable influence on health matters.

Existing Health Agencies

The American Red Cross, D. C. Chapter, engages in work similar to that in other metropolitan chapters except that perhaps the advantage of close association with the national headquarters is evident. Classes in first aid, home care of the sick, food selection and nutrition, are conducted in addition to the other important activities which are not properly included under health work.

The Association for the Prevention of Tuberculosis carries on its work through education and through the operation of a preventorium and fresh air classes. The annual budget is twenty-five thousand dollars, which is secured from the seal sale and from voluntary contributions.

The Child Welfare Society conducts nutrition classes for undernourished children, dental clinics for the care and treatment of their teeth, and mental hygiene classes for the correction of abnormal tendencies. The annual budget is approximately thirty thousand dollars, secured from voluntary contributions and in part from congressional appropriations. Ten health centers for white and colored mothers and children are in operation.

The Instructive Visiting Nurses Society provides nursing care for the sick, and instruction in the principles of hygiene and sanitation, prenatal and post-natal care. The work is carried on by graduate registered nurses, and the organization is supported by voluntary contributions, the budget amounting to approximately forty thousand dollars per year.

The Social Hygiene Society of the District of Columbia cooperates with voluntary and government organiza-

tions in dealing with legislative, educational and medical measures for the prevention and cure of venereal diseases. The Society also is interested in the non-medical phases of social hygiene including positive sex education.

The Society for the Prevention of Sickness is an organization of scientific men for the dissemination of information concerning milk and the feeding of infants. The principle work of the organization is to send to every mother, immediately following the registration of birth of her child, a pamphlet of instruction concerning infant feeding.

The District Health Department functions as a regular municipal department, including the usual bureaus and service. One tuberculosis clinic and one venereal disease clinic are in operation.

The District of Columbia Cancer Committee engages yearly in a vigorous "Cancer Week" campaign.

The Endorsement Committee on Welfare Organization is similar to that which exists in certain other cities to protect the public against fraudulent and inefficient social agencies. The committee is appointed by the commissioner of the District of Columbia from the membership of the Board of Trade, the Chamber of Commerce, Merchants and Manufacturers' Association, the Rotary Club, City Club, Federation of Citizen's Associations, Kiwanis Club, Women's City Club, Twentieth Century Club, and the "general public." In other words, the committee represents the people who contribute funds for the support of social and charitable organizations. The committee has set up standard requirements for the approval of social and philanthropic societies. These are as follows: (1) Filling a need sufficiently great to warrant equipment and support of a separate institution. (2) Local concern governed by a board of responsible and reputable people in actual control of its local affairs. (3) Accurate financial accounts open to inspection by this committee. (4) Expenditures not out of proportion to result accomplished. All approved organizations are furnished with endorsement cards signed by the officers of this committee.

The Washington Council of Social

*One of a series of similar studies regarding state health organization.

**A description of the nine Government bureaus engaged in public health work is contained in reports issued by the Washington Office of the National Health Council.

Agencies was organized in 1921 for the promotion of cooperation and a mutual understanding among forty private agencies and nineteen public agencies engaged in local welfare work. Not all the agencies in the District of Columbia engaged in social work are members of the Council of Social Agencies, some having remained out of the Council on account of financial restrictions. The members of the council contribute a small proportion of their budgets to the support of the council which maintains an office and a secretary. Voluntary contributions also are received by the Council, at least in its initial stages. The objects of the council are described as follows:

(1) To encourage and develop cooperation of social and civic agencies, and to correlate the social work of the District of Columbia.

(2) To increase the efficiency of social agencies and social work generally in the District of Columbia.

(3) To study social problems.

(4) To secure publicity of, and to endeavor to educate the public to a better understanding of social work in the District of Columbia.

(5) To act as an advisory council to social agencies in the District of Columbia.

(6) To provide for neglected social needs in the District of Columbia.

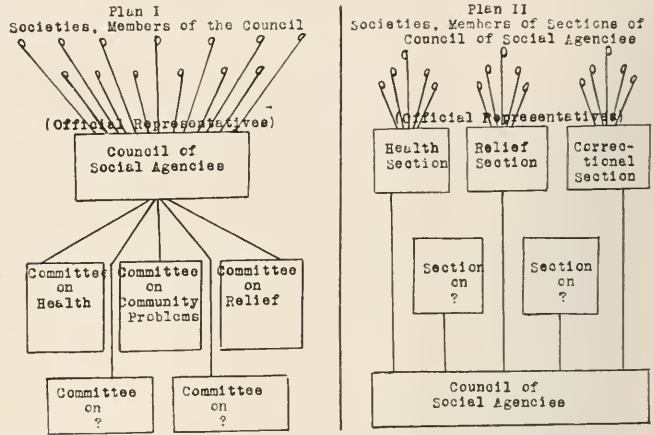

(7) To do such things or engage in such other activities as may be determined necessary to the general interests of social welfare, charity and philanthropy in the District of Columbia.

The forty private and nineteen public agencies which make up the Council may be classified under homes, orphanages, and boarding institutions, charitable relief organizations, child welfare agencies and day nurseries; correctional institutions, dispensaries and hospitals; religious education institutions, prisoners, aid, probationary and protective agencies; settlements and social centers; organizations of war veterans, and health agencies. It will be seen from this general grouping that the Council of Social Agencies includes practically every kind of social, health and relief organization.

The council functions through standing committees known as the Community Committee, the Family Welfare Committee, the Health Committee and the Children's Committee, but additional committees are appointed from time to time to study special problems and to make recommendation as to action which should be taken.

Several of the members of the health committee of the Council of Social Agencies are organizations which are not primarily or exclusively interested in the promotion of

ALTERNATIVE ARRANGEMENTS OF GROUPS IN COUNCIL OF SOCIAL AGENCIES

Two points of view have been brought out regarding health organization: (1) That no hard and fast line can be drawn between agencies engaged in health work and others devoted to social work; and (2) that health agencies dealing with technical scientific questions can accomplish most by focusing on specific health problems, and that wider coordinations lead only to confusion. The distinction between one point of view and the other is well illustrated in the two diagrams shown.

health. Thus the Y. W. C. A., Y. M. C. A., and Boy Scouts, are included in the membership of the Health Committee. The functions of the health committee are to consider health problems, especially those which involve cooperation or coordination, and to make recommendations to the council.

Perhaps the disadvantage under which the health agencies, members of the Council of Social Agencies, operate in their connection with the council is that no clear distinction has been drawn between specific health agencies and the other agencies which have an interest in health work. The affiliation of members of the council is first of all with the council itself and only secondly with a special division of the council, such as the health committee. The question may be raised as to whether it would be better in the interests of coordination of health activities and the strengthening of agencies engaged in health work to have the line of affiliation from the individual health agency direct to the health committee and then from the health committee to the council.

But those who are most strongly in sympathy with councils of social agencies point out that no hard and fast line can be drawn between certain agencies engaged in health work and others engaged in social work. These persons have felt that it is not advisable to separate health organizations into compartments by themselves, out of contact with other agen-

cies. On the other hand, it is urged with equal conviction that health agencies dealing with technical scientific questions can accomplish most by focusing upon specific health problems and that an attempt to coordinate very large and varied groups of social, relief, and health agencies, results only in vagueness and confusion.

The distinction between one point of view and the other is perhaps best illustrated by the diagram shown.

The advantage of the Council of Social Agencies in a situation such as exists in the District of Columbia lies in the fact that it is possible to provide an executive to promote friendly relations and cooperation among a group of agencies. If the executive is sufficiently trained in health work to understand the problems of coordinating health agencies it would seem advantageous for health societies to join in a central council for social agencies, provided such health societies are not able financially to support a trained executive officer among themselves for the promotion of their special interests. Where state health agencies are sufficiently strong to organize a separate health council and employ a competent executive, that executive can keep in touch with other social and philanthropic agencies and can insure cooperation wherever cooperation is feasible. But in any case the health council can usually with advantage affiliate itself with a general council of social agencies where such exists.

Rural Welfare Work of Mexican Government

Department of Agriculture Sends Hygiene Exhibit to Sons of Soil

By HELEN BOWYER, MEXICO CITY, MEXICO.

AMONG the most modern-minded and constructive of Mexico's high government officials stands Señor Ramon P. de Negri, in charge of the federal department of agriculture. His program for the upbuilding of farming in his country includes not only scientific attention to land and seed and stock but attention, as well, to the men, women and children upon whose health and intelligence the basic industry of the republic must depend.

As a first step in working out his plans for their well being, he has organized a campaign in behalf of the rural family which is already well started on its itinerary among the villages of the central states. It centers round an exhibit of some hundred posters on hygiene, food values, housing, child care, cleanliness, and the value of education. Some of them were adapted from posters of the American Red Cross, National Tuberculosis Society, Children's Bureau, Woman's Bureau, National Society for the Prevention of Blindness, Child Health Organization, and other important agencies in the United States. But a large number are originals evolved from the conditions and needs of Mexico itself. All are hand made in colors by leading artists of the capital, and form as vivid and expressive a collection of pictures of their kind as can be found upon the continent.

Two cars, granted for the purpose by special order of the President of the Republic are carrying the exhibit to the *campesinos*. One car is fitted up to serve as the exposition hall in those tiny rural centers where no suitable public building exists; the other serves as living quarters for the four young women who form the commission in charge of the campaign. This latter is provided with a kitchen and a cook so that the commission may carry its message to those frontiers of civilization where enlightenment is most needed.

To the American social worker, few things could be more basically dramatic than the visit of the campaign to one of the more isolated and primitive of the communities along its route. Ajusco, for instance, a little

mountain station some two miles above the level of Broadway, is composed of the station agent's house and office in a couple of box-cars and straw huts for the section hands. At first glance one would wonder what the commission could find to do in the five days' stay which time they informed railroad authorities they wished to leave their cars on the siding.

But a little way off, on the slope of the foothills of Ajusco, the old cloud-blanketed volcano which gives its name to the region, the dazzling sunlight disclosed the white walls of a large and scattered village. This under the guidance of the station agent's interested and energetic wife, two members of the commission canvassed, calling at every house and personally inviting the mothers to the exhibit and conferences and the children to the playground, which in the meantime other members of the party were installing in the beautiful mountain meadow that sloped upward from the railroad tracks to the tree line on the hills.

Erect Own Playground

That playground is a revelation to young Mexico. Outside of the one maintained in the capital by the International Playground Association and here and there some apparatus in the patio of a mission church such a thing scarcely exists in Mexico. It

is hard to say if the sliding board or the swings afford more delight but the honor of being first copied must go to the flying machine. In the second village the campaign visited the commission was overjoyed to run across a very creditable merry-ground in full swing beneath the weight of five or six hilarious young Indians who, taking full note of the construction of the one the commission had brought, had begged a tall iron tube and a wheel from the station agent and set up the beginnings of a permanent playground for community use. Little by little they intended to complete their equipment till they had apparatus similar to that in the meadow by the tracks, they said.

Inquiry developed the fact that just back of the low hills around the station lay other hamlets and these the commission also visited—on foot, on horseback, in the section car, by any means of transportation that offered. Nothing could exceed the simple good faith with which they were received. "It does not cost a single cent. It is a fiesta which the government is sending you free out of interest in your welfare," were the last words of the commission members as they took leave of each group. And though never perhaps in their experience had any former government sent such a message to them, they now listened trustingly.

Housed in box cars the exhibit travels to out of the way mountain villages.

In the ancient palace of Cortez whence came only cruelty and oppression to the children of the land is now located the rural family welfare commission, established by the Republic of Mexico for its people.

The villagers of Topelejo who could not spare from their fields the whole day that the visit and the journey would consume sent a message by their mayor that if the commission would remain until Sunday, the village would turn out in a body.

Among the attractions of the exposition the modest phonograph ranks high. At this season of the year night falls early in the *Valle de Mejico* and on its high mountain rim it falls very cold. But at five o'clock the darkness which has swallowed up the exhibit car is broken by pale patches of sombreros and white campesino trousers under enveloping blankets as the men of the community gather round the door. Inside, in the dimly lighted car—for here electricity is unknown—black shawled women with their children are squatting packed upon the floor, their eyes absorbedly turned upon the magic box from which the strains of *La Golondrina, Mexico*

Bello, and *El Sitio de Queretaro* come singing as by miracle to them. Within a day or two the more adventurous of the men have mastered the mechanics of the thing and can take charge of the Sunday concerts while the commission is exhibiting the bedbug, the head louse, the body louse, and other noxious enemies of the race to astounded little groups gathered round the microscope.

Locale Sign of New Day

At the moment of writing, the campaign is in Cuernavaca, the indescribably beautiful little capital of the State of Morelos. Here again a sense of the dramatic overtakes the social worker. For the locale to which, through the warm cooperation of the Governor, the commission has moved its equipment is the legislative chamber of the ancient palace of Cortes. That from this towered and ornate pile from which proceeded little

but slavery and cruelty to the children of the soil before the revolution should now come the first steps of a campaign to make them free and strong and happy is a sign of the new day which with time and peace her leaders hope to bring to the people of Mexico.

Dengue Fever Prevalent in the South

The wide prevalence of dengue fever in the South is emphasized by replies from a number of municipal health officers to whom the Metropolitan Life Insurance Company sent inquiries early in November asking for statements of the number of cases and deaths in Southern cities. These replies indicate that the 1922 outbreak of this disease is the most serious that has occurred in the United States since the Galveston epidemic of 1897 when twenty thousand people were attacked within two months.

The *Statistical Bulletin* of November, 1922 states that the worst report from the standpoint of fatal cases is that from Houston, Texas, where, within a period of a little over four months beginning in July, 575 cases were reported with nineteen deaths. The health officer of this city estimates that there were many thousands of additional cases, of a more or less mild form, which did not receive medical attention, and which, in consequence, were not reported to the health department. In Birmingham, Ala., there were 981 cases reported in October with two deaths. In Tampa, Fla., 1,060 cases with one death occurred in a five months period. In Macon, Ga., the health officer estimates that there have been between twenty and thirty thousand cases with four deaths. Reports received from other cities are as follows: Dothan, Ala., had 272 cases in the city and surrounding country; Montgomery, Ala., 137 cases; St. Petersburg, Fla., 2,000 to 2,500 cases; Albany, Ga., 68 cases, which the health officer estimates to be about 20 per cent of the actual number; Brunswick, Ga., 608 cases; Vicksburg, Miss., 205 cases; Beaumont, Tex., 4,175 cases; Galveston, Tex., 255 cases.

Several of the health officers state very frankly that the number of cases reported gives only an inadequate picture of the prevalence of the disease. In some cities it is not reportable, and even in those where it is reportable, hundreds or thousands of cases are not given medical treatment, and do not get into the health department records.

Young Indians of Tres Marias, not to be outdone by the commission playground, built for themselves a merry-go-round from a tall iron tube, a wagon wheel and ropes.

Development of Vital Statistics in Canada*

The Demand for Facts Has Now Been Met by Properly Collated Data

By E. S. MACPHAIL, SUPERINTENDENT, DOMINION BUREAU OF STATISTICS, OTTAWA, ONTARIO.

VITAL statistics in Canada being the product of systems of registration, a short review of these systems in the early days is essential. The collection of vital statistics in Canada, as in most countries, commenced with the recording of baptisms, marriages, and burials by the parish priests. These registrations, instituted solely for ecclesiastical purposes, were without reference to their statistical value. Indeed, at that time they had no statistical value.

In the province of Quebec the preservation of these registrations makes it possible to have a continuous record of births, marriages, and deaths from the founding of the colony on the banks of the St. Lawrence in 1610 to the present. More than fifty years before Captain John Graunt compiled mortality statistics for London, England, the priests of Quebec made reports to their superiors of the numbers of births, deaths, and marriages occurring within the year in their parishes. It is obvious that these were not "vital statistics" as the term is now understood. Even at the present time "Registration" and "Statistical Collection" are two different and distinct things in Quebec—the former is an ecclesiastical function, the latter a civil one.

In the early days there were no regulations as to the manner in which these registers should be kept. There is, however, no doubt that a complete record of every marriage, death, and viable birth was made. In 1678 a code of regulations was prepared which provided that these records should be made in duplicate, one copy to be delivered to the civil authorities in the month of December each year. This arrangement was continued after the cession of the country to Britain and was, by statute, extended in 1793 to the newly established Protestant congregations. This Act with but few slight changes constitutes the civil instrument under which the province of Quebec now obtains the data for its annual vital statistics report. The mortality returns thus obtained are fairly complete, with the excep-

The Draft Vital Statistics Act with its annexed schedules has been utilized in Canada to form the basis for legislation in the several provinces to secure uniformity of procedure and comparability of results.

Standard forms, perfected by the Dominion Bureau, are supplied free of charge to subdivision officials so that it remains for only a single province to conform to suggested standards to bring about statistical results in Canada comparable with those of other countries.

While Canada did lag somewhat behind some countries in the collection and publication of vital records, a complete system has been envisaged so that the causes of fluctuations may be reached through the analysis of the data that now are well in hand.

tion that the cause of death is not always covered by a medical certificate. Births and marriages are reported by totals only once a year. There are no individual returns made for either births or marriages.

In English speaking Canada the registrations of births, deaths, and marriages were from the commencement seriously defective. The pioneer settlers, often going out into the wilds, far from the ministrations of religion and centers of civil authority, were not much interested in making official reports of births, deaths, or marriages. In Ontario the registration of anything more than deeds had hardly begun before 1860. In that year an act was passed for the collecting and safe-keeping of the records of all marriages celebrated in the province. But as the law provided that the clergyman should pay one dollar for each registration made, its failure was a foregone conclusion. In 1868 legislation was enacted for the free registration of births and deaths. Since then Ontario has given a great deal of attention to its vital statistics legislation and has been from year to year extending its scope and perfect-

ing its procedure. In 1871 the province commenced the compilation and publication of statistics of births, deaths, and marriages and has been in favorable comparison in this regard with other countries having a progressive vital statistics program.

Until quite recently births and deaths were not officially recorded in Prince Edward Island or New Brunswick. It was much easier to find the natal history of a pure bred "silver fox" than of a child. It was not thought necessary to have any record as to when a death occurred and the cause of it; that there might be a vague reason for registering a birth, but "What sense was there in keeping an official record of when a person died or the cause of death," sums up the general attitude regarding the registration of births and deaths in some of the older provinces.

In Nova Scotia, as early as 1761, legislation was passed providing for the registration of births, deaths, and marriages. In so far as births and deaths are concerned the act remained a dead letter for several years. Marriage registrations contained merely the name of the bride and groom. It was not until 1864 that official returns of births and deaths were made compulsory.

The prairie provinces, being settled at comparatively recent dates, had from the outset established systems of vital statistics based largely on the systems in vogue in countries where the most modern ideas prevailed.

In British Columbia the collection of vital statistics had its inception in 1872 and the first report was issued in 1874. The act and schedules were modelled after those under which Ontario operated.

Having briefly sketched the beginnings of registration in the several provinces and the making of returns of births, deaths, and marriages for statistical purposes, we may for a moment or two review the part played by the Dominion in this field.

The legislative authority of the Parliament of Canada and of the several provinces is delimited by the British North America Act, 1867. Under this instrument "Property and

*Read before the Fifty-First Annual Meeting of the American Public Health Association, Vital Statistics Section, Cleveland, O., October 18, 1922.

Civil Rights" falls within the jurisdiction of the provinces. And because vital statistics—or rather the registrations from which the statistics of births, marriages, and deaths are compiled—are essential in the transfer of property and the establishment of civil rights in general, each of the nine provinces had, as outlined above, for some time, passed legislation more or less effective on the subject. Concurrently, however, the British North America Act assigned "Census and Statistics" to the Dominion Government. In the original Census and Statistics Act, the Office was assigned two definite functions: (1) to collect a record of all persons deceased within the census year; (2) to coordinate and collate the vital statistics collected annually by provincial or municipal agencies. Thus two kinds of statistical activity were imposed on the Office; (a) independent inquiry in census years as to deaths and (b) annual collection and publication of births and deaths in collaboration with provincial or municipal agencies.

The collection of mortality statistics was a feature of every census from 1871 to 1911. In no instance were the data collected worth the time and money expended on them. Nevertheless, in spite of the inherent unsoundness of securing at a decennial period a record of deaths the practice was continued until 1911, when the obviously inaccurate character of the results led to the discarding of the data obtained. The inquiry has been omitted from the population schedule of the Sixth Census.

No Permanent Machinery

Turning to the second kind of activity enjoined on the Census Office—the collecting and collating of vital statistics in cooperation with provincial and municipal authorities, it may be stated that, while the framers of the original Census Act provided for an undertaking which could only have been successfully carried out by a permanent bureau, yet not until 1907 did the newly created Bureau of Statistics known first as "census and statistics office" provide the necessary machinery and staff to give effect to the provisions of the act. For every decennial census previous to 1911 a new staff from director to messenger had to be assembled. It was, therefore, impossible for an office which had not a permanent existence to co-ordinate the vital statistics of Canada through cooperation with provincial agencies even did the several provinces provide the means for such an undertaking. It requires time, pa-

tience, and a trained staff to make a complete study of the problems involved and to prepare a concrete proposition which will constitute a working basis for cooperation as between federal and provincial bureaus—each of the latter with a system more or less satisfactory to itself, but providing data incapable of collation with the data of other provinces for a comprehensive national statistic comparable with the vital statistics of other countries.

It may be interjected here that in 1883 under the provisions of the "Census and Statistics Act," the Dominion instituted a plan for compiling and publishing the annual mortuary statistics of cities of 25,000 and over by direct arrangement with the municipalities. The annual reports resulting from this arrangement gave the statistics of mortality by sex, age, conjugal condition, occupation, and cause of death. This system was first applied to five cities—Montreal, Toronto, Hamilton, St. John, and Halifax and later it was extended to twenty-one others. Upon the organization of provincial bureaus of registration this work was abandoned. In many instances the work carried on under this plan of cooperation was not replaced by provincial or municipal organizations.

A few months after the abandonment of this plan for statistical cooperation between federal and provincial agencies, a conference of Dominion and provincial officials held in 1893 passed a resolution calling upon the provincial and Dominion authorities to cooperate in the work of collecting, compiling and publishing the vital statistics of the Dominion. This resolution had, however, no immediate results because, as previously stated, there was no permanent agency to give it effect. Provincial jealousy precluded any one province taking the lead. Each of the old provinces (except New Brunswick, which had no vital statistics) enacted its own legislation on vital statistics and administered such legislation according to its own individual methods. In one province road masters were appointed registrars.

Because some of the provinces did not collect statistics of births, deaths, and marriages and, even more, because of the incomparability of facts collected, of methods of collection, of diversity of forms, and of standards of enforcement, Canadian vital statistics remained extremely unsatisfactory and impossible of collating on a national basis up to 1920.

It was on the principles laid down

in the resolution of 1893 that the Bureau of Statistics in 1918, under the guiding hand of Mr. Coats, Dominion statistician, attacked successfully the problem of nation-wide vital statistics for Canada. The creation of the Dominion Bureau of Statistics and the general statistical organization which was planned as a result provided the primary motive power.

Draft Statistics Utilized

After a thorough canvass of the vital statistical situation in every province, conferences of Dominion and Provincial officials were held in June and December, 1918. At these conferences it was agreed; (1) that the Draft Vital Statistics Act with its annexed schedules prepared by the Dominion Bureau of Statistics should form the basis of the vital statistics legislation of the several provinces, thus securing uniformity of procedure and comparability of results; (2) that the provinces should undertake to obtain the returns of births, deaths, and marriages on prescribed forms, as approved and adopted by the conference. The Dominion Bureau of Statistics to print and supply the forms free of charge; (3) that the provinces should forward monthly to the Bureau either the original returns or certified transcripts; the Bureau to undertake the compilation and publication of the results on national lines. Eight of the nine provinces approved of the plans proposed and have lent every aid possible to make the undertaking successful.

The year 1919 was employed in perfecting the forms, printing and sending them to the various Provincial Registrars for distribution to subdivision officials. Beginning with January, 1920, the returns of births, deaths, and marriages were made on practically similar forms in each of the cooperating provinces and we have reason to hope that Quebec, the pioneer in establishing systems of registration in Canada, will shortly find it possible to reconstruct her system along the lines of the "Model Draft Act" and have returns collected on the standard forms, and so round out a uniform system of vital statistics for the whole Dominion. On this point I have not much fear for Quebec has been noted in recent years for vast strides in modern statistical methods in other fields.

It will be noted that the Dominion Bureau of Statistics prints and supplies free of charge to the provinces, not only the three main forms from which the compilations are made, but

all the other forms incident to a system of vital statistics, such as physician's notices of births and deaths, and cemetery returns. The Bureau has also secured the free transmission through the mails of all statistical returns which are ultimately intended for the Bureau of Statistics.

Free postage is, of course, an absolute necessity if we ever hope to have a better than 90 per cent complete registration. I think it may be safely said that the Bureau of Statistics planned along comprehensive lines. The provinces have not been slow in availing themselves of the advantages the plans projected by the Bureau for collating the vital statistics of Canada provided. No matter how wisely and generously the Bureau planned, the success of the venture was largely in the hands of the provinces, and our present position is a credit to their spirit of cooperation.

First Annual Report in 1921

Owing to difficulties incident to launching a new scheme, perfecting the machinery, and the necessary ironing out of the inevitable unforeseens, the Bureau found it inadvisable to do more than compile a general summary of births, deaths and marriages for 1920—our first year of cooperation. These mimeograph summaries were not generally distributed, but were submitted to the registrars of the cooperating provinces and others interested in vital statistics for criticism and suggestion.

Our first annual report, covering the calendar year, 1921, for the registration area, which comprises eight of our nine provinces, was completed in December, the preparation of it being somewhat delayed owing to the Bureau having undertaken to make all compilations for five provinces. In two instances the request to undertake this work was not made until July. Consequently it became necessary to re-compile some of the tables a second time to obtain the data for the smaller areas which is essential for local surveys. The Bureau gladly acceded to the request and has completed the compilations for these provinces in agreement with the general plan adopted for the publication of the national tables. For five provinces the statistics published by the Bureau and the provinces will be alike in all respects except that the compilations for the provinces will be prepared for counties, cities and towns, while the national tables will only cover the provinces, cities and towns of five thousand and over. For

the other three provinces, which are doing their own compilations, we have exchanged results so that as far as possible the statistics issued by the Dominion Bureau of Statistics and the provincial offices will tell the same story.

For 1921 we issued monthly statements summarizing the results for the eight cooperating provinces. For this year we have had temporarily to discontinue these monthly summaries owing to having undertaken, as noted above, for the Maritime provinces, Ontario, and British Columbia, the compilation of the tables for their annual vital statistics reports.

When the idea of cooperation was first presented to the provinces one of the conditions was that they should undertake to obtain a better than 90 per cent full registration. We believe that in nearly all the provinces they are doing a good deal better than this for deaths and marriages and are well up to the standard for births. We are at present working out a plan to check the fullness of the returns made by each province.

While Canada lagged somewhat behind some countries as regards the collection and publication of national vital statistics, yet when we did commence we envisaged a complete system. Our past and present position may be summarized as follows:

In 1918 six provinces were collecting returns of births, deaths and marriages according to varied legislation and widely differing forms—one province without any and another province with a system so bad that only intermittent reports were issued.

Vital Statistics on 70%

In 1921 the "Model Bill" was accepted by eight provinces as the basis of vital statistics legislation and the returns of births, deaths, and marriages are made on standard forms in these provinces.

In 1922 a system of *Monthly Reports* for Canada is provided for and in operation. Other achievements are: (a) The first annual report* covering eight of our nine provinces is prepared and ready for publication; (b) five of the eight cooperating provinces accepting the Bureau's compilations, thus insuring similarity of results and confidence of the public in the credibility of the statistics; (c) a report covering 70 per cent of the population of any country is fairly indicative of the whole; thus, for the first time an opportunity is provided of comparing Canadian Vital Statis-

*Copies of the First Annual Report will be sent on request.

tics on a national basis with other nations similarly situated.

In all our planning to secure a basis of cooperation as between the Dominion and the provinces which would make possible the collating of the returns from every province into a harmonious national whole, we have always kept in mind the fact that a true national vital statistic is not a mere aggregation of the reported numbers of births, deaths, and marriages from each province, but that it involves a purview of the totality of these phenomena upon which in the last analysis national existence depends. In the first place, the Dominion Bureau of Statistics wished to collate the vital statistics returns of the provinces with the object of revealing their interplay and to discover, if possible, the forces that determine their fluctuations above or below normal; and second, that the statistics of births, deaths, and marriages might be properly articulated with each other so as to give as far as possible a general comparative survey of inter-provincial and international conditions as indicated by a proper presentation of the facts in a single conspectus. The venture has proved highly successful; we have blazed a new trail in our statistical realm which at no distant date will be a well travelled highway where the finger posts will always point in the direction of greater efficiency.

Death Rate from Childbirth Lower in 1921

Death rates of mothers from childbirth or puerperal causes in 1921 were lower than in any year since 1917, compilations made by the Bureau of the Census show. For the nine states and the District of Columbia which constitutes the birth registration area of 1915, exclusive of Rhode Island, the death rate from puerperal causes in 1921 was 6.5 per thousand live births as compared with 7.6 in 1920, 6.8 in 1919, 8.9 in 1918, 6.3 in 1917, 6.2 in 1916, and 6.1 in 1915. The relatively high rates for the years 1920, 1919, and 1918 were doubtless due, for the most part at least, to epidemics of influenza which took heavy toll of pregnant women. The ratio of deaths from childbirth to the number of women bearing children in the year 1921 was about 1 to 150.

Of the 27 states for which figures are available, South Carolina has the highest 1921 death rate from puerperal causes of 9.8 per thousand live births and Connecticut the lowest, 5.3.

Morbidity in the Navy

THE epidemic of influenza that occurred in the United States early in 1922, first made its appearance in the navy among the personnel of ships in New York or in ships which had recently been in New York. The epidemiological evidence indicated that this was a continuation of the epidemic that had appeared in Europe a few weeks previously. According to the annual report of the

6.62 per cent. That the disease was very mild in character is shown by the fact that only ten deaths occurred as a result of this particular epidemic.

Another subject of interest dealt with in the report is the general morbidity of the navy for all causes for the year 1921. The admission rate for all causes was 624.65 per 1,000 per annum. This was lower than the

there were but four years in which the rate was lower than that of 1921. It will be noted from Chart 2 that approximately 70 per cent of the admissions were in classes III, VIII, XII, XVIII, and XXV. "Class XII, which includes only gonococcus infections, syphilis, and chancreoid, caused 19.18 per cent of all admissions; tonsillitis and bronchitis which are included in Class XVIII, caused 10.03 per cent and 7.55 per cent of the total admissions, respectively."

The noneffective rate for the navy for all causes was 34.52 per 1,000 per annum, or in other words, an average of 34.52 men out of every 1,000 were incapacitated for duty each day during the year.

Kansas City has 15,124 pre-school children, 14,844 of whom have been physically examined, according to the charities bureau of the Chamber of Commerce. This is an increase of 7,657, almost 100 per cent increase over last year. Of these children, 5,103 were under standard; 2,644 have been followed up and cared for, 1,842 by families, 802 by family physicians, clinics, or hospitals; 2,136 are still under observation. Only 323 cases are unreported. The work was done at an average expense of 74 cents per child.

The National Health Council has issued an extensive list of health films with their distributor, price, and synopsis.

INFLUENZA EPIDEMIC, U. S. NAVY. JANUARY 7-APRIL 1, 1922. RATIOS PER 1,000

Chart I.—Influenza epidemic, U. S. Navy, January 7 to April 1, 1922. Ratios per 1,000. Admission rates by classes, 1921. Ratios per 1,000.

Surgeon General, U. S. Navy, for the fiscal year 1922, it was first thought from the weekly morbidity rates, as kept in the Bureau of Medicine and Surgery, that February 11 would mark the peak of the epidemic, but soon afterwards reports from the Pacific Fleet were received in increasing numbers, together with reports from ships and stations on the Atlantic seaboard. The peak of the epidemic was finally reached on March 4. Following this date there was a rapid decline in the morbidity rates. The first attack was experienced in the Atlantic Fleet where the highest rates were in January, whereas the highest rates in the Pacific Fleet occurred in February. Chart 1 shows the weekly morbidity rates for the entire navy for January 7 to April 1, 1922.

The average complement for the Navy during this period was 128,951. A total of 5,352 admissions were recorded giving an admission rate of 166 per 1,000 per annum and an attack rate of 4.1 per cent. The attack rate for the 1918 epidemic was 15.08 per cent and for the 1920 epidemic

rate had been for the past three years and during the past twenty-two years

ADMISSION RATES BY CLASSES. 1921. RATIOS PER 1,000.

Chart II.—The classification of the diseases and injuries occurring in the U. S. Navy is as follows: I. Diseases of blood. II. Diseases of circulatory system. III. Diseases of digestive system. IV. Diseases of ductless glands and spleen. V. Diseases of ear. VI. Diseases of eye and adnexa. VII. Diseases of genito-urinary system (nonvenereal). VIII. Communicable diseases transmissible by oral and nasal discharges. IX. Communicable diseases transmissible by intestinal discharges. X. Communicable diseases transmissible by insects and other arthropods. XI. Tuberculosis (all forms). XII. Venereal diseases. XIII. Other diseases of infective type. XIV. Diseases of lymphatic system. XV. Diseases of mind. XVI. Diseases of motor system. XVII. Diseases of nervous system. XVIII. Diseases of respiratory system. XIX. Diseases of skin, hair, and nails. XX. Hernia. XXI. Miscellaneous diseases and conditions. XXII. Parasites (fungi and certain animal parasites). XXIII. Tumors. XXIV. Female diseases and conditions. XXV. Injuries. XXVI. Poisons.

Psychology of a Modern Venereal Clinic

Interviews, Records, Follow-up Must Gain Patient's Cooperation

BY BERNARD C. ROLOFF, EXECUTIVE SECRETARY, ILLINOIS SOCIAL HYGIENE LEAGUE, CHICAGO, ILL.

THE ultimate success of any venereal disease clinic depends upon many things. A good impression must be made upon the patient before he arrives at the clinic. If he is referred by a friend who has been a patient the good impression is already begun, but if a washroom notice is depended on to bring patients, its nature and appearance must gain the patient's confidence.

Washroom notices simply tacked to walls soon become dog-eared and dirty. The Illinois Social Hygiene League frames all such notices and nowhere do the words "venereal disease" appear in large or conspicuous letters. Two thousand of these are in Chicago industrial plants. Framing keeps them neat and clean and the wording is such that men and women do not feel guilty when seen reading them.

A clinic which depends on gaining patients through educational work rather than through coercion must study the type of educational work which is most productive. A study of two hundred of our latest cases disclosed as main forces driving patients in for treatment the following:

Sent by former patients, 36%; saw exhibit in city comfort station, 15%; sign on our building, 13%; dispensary notices in public places, 12%; educational work in shops and factories, 9%; referred by outside doctors, 7%; sent by charitable agencies, 4%; sent by state venereal disease bureau, 2%; newspaper article, 2%.

In 1921 conditions had varied. Sent by friends, 49.3%; sign outside, 15%; doctors and hospitals, 8%; city comfort station, 7%; employers washrooms, 5.7%; Municipal Pier, 5.4%; social agencies, 3.2%; miscellaneous, 2.6%; Y. M. C. A.'s, 1.2%; schools and libraries, 1.3%; newspapers, 1.2%.

The patient who comes in because he saw our sign outside the building gets his first impression from the sign, and the exterior of the building; his next from the looks of the entrance hallway, and his third from the appearance of the waiting room. Therefore, we have made all these as inviting as possible. The very atmosphere of the place must breathe friendliness.

The next and very important impression comes from the attitude assumed by the first person met by the patient, who is the admittance clerk. For a time we could not understand why some young fellows entered our front hallway and went right out again. It seems that the first person seen when the outer door opened was a reserved, modest but very pretty young lady stenographer. One look at that girl and many young fellows fled. The prospect of having to tell her what they came for was too much. So we secured a young man instead and changed the location of his desk so that the patient had to come all the way in before seeing anyone.

When a woman enters the clinic the first thing she sees is a sign "Women and Children Upstairs." Arriving there she meets the young woman social worker and may speak to her privately in a cozy little room. I have maintained all along that women and girls should be interviewed by women, treated by women and the follow-up letters written by women, and visits to homes conducted by a woman.

Humanizing the Clinic

The man admittance clerk must be a man to all men. Patients nearly always resent a multitude of questions; they view with alarm the ostentatious filling out of formidable forms. Therefore, the less ostentation and formality the better. A clever interviewer can, by simulating deep interest in a man's job, commiserating with him about the difficult nature of his specific task or the smallness of his pay or perhaps remarking flatteringly about the generosity of it, secure answers to this most difficult question even before he seats himself with the patient.

"By the way, jobs at the mills are rather scarce now," said our interviewer to a new patient even before the latter was aware he was being interviewed, "but some one told me they paid the rollers pretty big salaries." This threw the patient off his guard and in a moment he revealed willingly and even eagerly all the interviewer wanted to know about his job including the amount of his pay. It was easy to remember the details for a

few minutes and to enter them upon the record even before the interviewer had learned the patient's name and address. That patient was, of course, not accepted for treatment but was referred to a private physician because we protect in this clinic, most carefully, the practice of the private physician.

I do not want to bear too heavily upon those who are managers of purely medical clinics. My reasons for stressing the need for careful approach by the interviewer have grown out of our educational work. Our clinic is perhaps the only one in this country, at least that I know of, connected directly with a regional propaganda organization. We begin our attack upon the whole problem by means of education and therefore it is natural for us to treat the patient in the clinic with as much friendliness and give him or her as much attention and heart interest as we would if we had no clinic and the patient came in merely for information.

Our staff has spent hours with single patients having special problems. I gave two hours recently to a depressed patient to keep him from committing suicide. Ordinarily he would have seen the doctor, been curtly sent to a treatment table, treated, and sent home with "come again next week." We and our interviewers act as buffers between the patients and their troubles and between them and the doctor. We interpret the doctor's findings and directions to the patient; we interpret the patient's little worries to the doctor. We smooth the way with kindness; we grease the skids that shoot these afflicted men and women from worry and ill health out into the bright world where life is worth while.

Let's humanize our clinics. Doctors alone cannot do it. A clever medico-social worker can mean the difference between success and failure in a clinic. Tact, kindness and diplomacy are essential.

Our records are not as complete as they should be. We are rushed as other clinics are; our space is at a premium; our staff limited, but we find that we can get many facts—not in a regular interview, but just in be-

tween. Hardly an old patient comes in who is not inquired about kindly every time he comes—his family, his work, his ailment.

We have simplified our follow-up in this way: Every patient is checked through a cash register. That machine is part of our bookkeeping system. I have seen doctors throw their hands up in horror at that cash register. It has even been made the subject of complaint at a medical meeting. But it serves a purpose far beyond the taking in of a little money. It is part of our follow-up system. A patient enters on his first visit. After the interview he is checked through the cash register whether he pays or not. The little slip that comes out is handed him and he is told to return it to the admittance clerk before he leaves the clinic. After treatment, he being a new patient is likely to pass by the clerk, dropping his cash register slip and start for the door. Right then and there begins our follow-up work. "Wait a minute," calls the clerk, "What day did the doctor say you were to return?" "Why, I don't know, I never asked him" is the reply almost invariably given, even though the doctor actually *did* tell him when to return. "Go back and find out" the clerk urges. The patient seldom or never forgets after that to ask the doctor when he is to return. He cannot get out of the clinic without reporting the date of his next visit. This helps him to remember the time definitely. The clerk enters the date upon the little slip and puts it in the cash register drawer. The next day every one of those dates are

entered upon the little square in the follow-up record with a single pencil line.

Suppose that the same patient returns a week later, but not upon the right day. With the follow-up record before him the clerk asks, "You were due to return here Tuesday. This is Wednesday. Why are you a day late?" "Well, I had a date Tuesday." Right then and there he gets a friendly admonition on the great importance of regularity in attendance and how much more quickly we can help if orders are obeyed. And that patient and every patient gets the same persistent treatment.

At the end of the month all the cases that were due and did not come in that month are separated and gone over carefully. Those cases which are active and infectious are separated from the ones which have been discharged, given vacations, or who need not be followed up. Letter No. 1 is written on plain paper in a plain envelope. My own name and address is all that appears upon the notice. A curious landlady could steam the flap of such a letter and get nothing for her curiosity. This protects the patient. The second letter is more urgent. The third is upon our letter head and frankly, but in a kindly way, threatens reporting the case to the health department.

Here is some interesting data on how our system works. In 1919 we had no social work. In December, 1919, out of 430 cases, 146 failed to return. In January, 1920, a social worker was engaged.

The first letter brings back 50 per

cent of the cases absent without leave; the second 25 per cent more, and the third 20 per cent more. About 5 per cent of those absent without leave do not come back.

The final follow-up is, of course, a health department job. If we know where a patient works, if he works, it is easy enough to appeal to the employer, but that is seldom necessary.

TABLE SHOWING HOW SOCIAL WORKER DECREASED FAILURES TO RETURN FOR TREATMENT.

Month	Patients Treated	Failed to Return
January, 1920	548	154
February, 1920	435	80
March, 1920	595	48
April, 1920	532	56
January, 1922	600	6
February, 1922	620	4

Human service pulls heartstrings. Any good clinic having good medical service fortified by the right sort of social service may, by securing co-operation of patient through the exercise of common sense and kindness, make a success of its task,—that of restoring to industrial and familial efficiency the unfortunate victims that come to it. Our task is not complete when we merely sterilize a patient so as to render him non-infectious; we must do a complete job or the expensive medication and service originally given are almost wasted. We aim to keep our syphilitic patients in sight for five years. Our clinic is now treating case No. 10,000, but cases Nos. 4, 36, 175, 200, 301, who began treatment in 1918, and many more, scores of them, are still coming for treatment or periodical examination.

The County General Hospital

THAT county general hospitals, authorized by state laws and supported by tax levied on the people of the community, are helping solve the rural medical problem is attested by the success of four county hospitals established since 1918, three in Missouri and one in Kansas. These hospitals are modern in every detail and are open to all legal practicing physicians.

The hospitals of Audrain, Boone, and Callaway counties, Missouri, located at Mexico, Columbia, and Fulton respectively, were established under a law, modeled after the Iowa and Indiana statutes which passed the Missouri legislature in 1917. Provision is that any county may vote bonds and a tax for the erection and maintenance of a county hospital,

trustees to be non-partisan, and practice in said hospitals to be open to all practicing physicians.

The Boone County hospital at Columbia, Mo., was opened December 15, 1921 and in the first five months of service received 275 patients. Service and equipment includes a staff of graduate nurses, a superior culinary service, an x-ray department, and laboratory. The Boone County Medical Society supplies a volunteer visiting staff. Quarterly alternating services are maintained in internal medicine, general surgery, obstetrics, pediatrics, genito-urinary and skin, gynecology, x-ray and laboratory. The society also supplies lecturers on public health and preventive medicine and volunteer inspectors of public school children. In the staff meeting room on

the fourth floor of the hospital are held the meetings of the county society; the room is open to any meetings with a health aim.

An example of a successful county hospital in another state is the McPherson County hospital, McPherson, Kas., which was constructed at a cost of \$152,000. In speaking of its work, Dr. L. F. Quantius says:

"Country people are entitled to as efficient medical and hospital service as are city people. The county hospital supported by public taxation and open to all members of the community seems a logical remedy for the lack of adequate medical service. It can give our physicians and surgeons facilities for special training and serve also as an invaluable center of health education."

Colorado's Station to Station Clinic*

By ELLA CYRENE BAKKE, PUBLICITY SECRETARY, COLORADO TUBERCULOSIS ASSOCIATION, DENVER, COLO.

WE HAVE heard of traveling clinics in some states where children are examined while the truck waits, but a station to station clinic has recently been demonstrated in three Colorado towns. No single state agency could have financially afforded to conduct such a demonstration, but the extension division of the University of Colorado, cooperating with the Colorado child welfare bureau, the state board of health and the Colorado Tuberculosis Association, was able to carry on two-day community conferences and exhibits in the towns of Limon, Elizabeth, and Castle Rock. These three towns were chosen for experimentation in order to decide upon a satisfactory method for a state organization to serve a small community. Another reason for choosing them was that they were so located as to make them conveniently accessible for the transportation of equipment.

The plan for a week of such conferences was briefly this: The University extension division, through its secretary, Charles I. Madison, made the first contract and secured a guarantee for \$50 to cover local expenses. The proposition was presented to commercial clubs, Lions clubs, women's clubs and other organizations, including school boards and churches. After a great deal of persuasion and explanation that these four agencies were not working for any personal gain and that the visiting physicians were not looking for business, local committees were formed in each town to make arrangements to carry on the publicity and to assist the state workers. Program for the meetings in each town included: (A) Conference on child welfare, public health, community problems; (B) free physical examination of children under school age and as many of school age as time permitted; (C) exhibits dealing with child welfare, public health, recreation.

The conference opened the first evening with an address by Mr. Madison on community leadership, emphasizing the community's health, recreation, and attractiveness. The phase of the community's health dealing with the school child was presented by Miss Bakke, publicity secretary of the Colorado Tuberculosis

Association, in an illustrated lecture on "Nutrition for Children." She suggested the nutritional class method for developing the underweight child and advised mothers to have their children examined and to provide rest periods and lunches for them.

The physical examination of children was certainly the most spectacular part of the conference. Three child specialists from Denver were employed by the child welfare bureau to examine the children one morning in these three localities, Dr. R. P. Forbes at Limon, Dr. J. C. Savage at Elizabeth, and Dr. Elsie Pratt at Castle Rock. A total number of 154 children were examined by these physicians: Limon 50; Elizabeth 71, including 24 high school children; and Castle Rock 33. (Dr. Savage remarked about the eagerness of high school children to be examined.)

Results were very similar in each locality. The condition of the babies was usually very good, but about one-half of the children from two years to high school age were underweight. Children examined were selected by their teachers or parents and therefore cannot be considered the average. It would probably be safe to conclude that if all the school children had been examined, one-third of them would have been found 7 per cent or more underweight.

Find Bad General Habits

During examinations, opportunities were given to parents to discuss with physicians and assistants the care of their babies, removal of defects, and general nutrition. Conference workers were amazed at the large number of children who had to get up as early as five and six in the morning to help with chores before they caught the transportation bus to the nearest consolidated school. It was gratifying to learn that in the town of Elizabeth, the primary teacher offered to make arrangements for a rest room in the school where not only the underweight children would be required to rest but also those whose working days were from five in the morning until nine at night.

Physicians found that while the general appearance of the children was cleanly, dirty teeth and dirty finger-nails predominated, and the general health habits, such as irregular eating, candy between meals, tea and coffee, home study and over ac-

tivity, prevailed. Although the retiring hour was earlier than in Denver, there were very few children even among the pre-school group who took rest periods during the day. Lack of home control was ever present. Children of the leading citizens were just as much underweight as those of the three dollar a day laborer.

At the afternoon meetings the physicians gave very practical and understanding summaries to the parents of the conditions they had found. They discussed in seminar fashion the problems of individual children whenever the parents requested it. In a friendly yet dignified manner they made the mothers realize that they were guardians of their children's health and should begin by teaching them sane and regular health habits.

Closely correlated with the summary of the physicians were the talks given by Mrs. Dick of the child welfare bureau on the "Colorado Plan for Maternity and Infancy" and Miss Livsey, state supervisor of nurses, on "Why a Baby Conference." The former explained that the Sheppard-Towner act provides funds for the care of mothers and babies when the amount is met by a state appropriation. Because of Miss Livsey's experience as a county nurse in Colorado for four years, she was able to give the mothers many valuable suggestions. The fact that she had been able to check an epidemic of smallpox by discovering a teacher in a rural school broken out with the disease could not help but emphasize the value of a nurse in the community.

Mrs. Matthews, executive secretary of the child welfare bureau, gave a resumé of the children's institutions throughout the state and cited several cases where the bureau had been responsible for the treatment of crippled children. She emphasized the importance of birth registration.

Mechanical devices and posters not only served to attract attention, but illustrated the concrete work of the organizations. A member of each organization was in charge of her exhibit to explain in detail material represented.

Members of the conference feel that having five trained workers and one physician spend a day and a half conducting health conferences in a small community has been worth the time and expenditure.

Such a conference made a demon-

*Read before the Colorado Community Conference and Exhibit, Limon, Colo., November 20, 21, 1922.

Among the exhibits used by the station to station clinic were the breathing dolls. Fumes representing exhaled carbon dioxide were pumped in equal quantities through the nostrils of both dolls. The pictures point the lesson.

stration to the community of the importance of the individual's responsibility to the community's health, awakened local citizens to the actual needs of the children, and taught them methods of caring for them.

An awakened interest in measures of public health and the possibility of carrying on a definite piece of work has resulted from the conferences. The outcome will doubtless be some permanent health work, community or county nurse, health center, monthly clinic, nutritional classes in the schools, hot lunches, and other health

work in the schools. If but one child's health has been saved, the work has been worth while.

The experience of that week was decidedly educational to the workers themselves. They all agree that some uniform examination blank should be adopted, simple in phraseology and explanatory to the parent as well as detailed enough for the physician. They further agree that the technic of the clinic should be worked out systematically in order to secure maximum results with a combined staff of trained and untrained workers.

Eye Clinic Follow-up Work

ALTHOUGH medical science has progressed far in the development of methods of treatment for diseases of the eye, it is common knowledge that much preventable blindness exists. With a view to ascertaining present conditions and developing desirable standards, leading ophthalmologists of the city of New York have organized as the ophthalmological section of the Associated Out-Patient Clinics, with Dr. Walter E. Lambert as committee chairman and Dr. Conrad Behrens, Jr. as secretary. The study was made under the supervision of the committee by Dr. Gertrude E. Sturges and Miss Elizabeth Tandy of the staff of the Associated Out-Patient Clinics.

To discover the proportion of typical cases of eye diseases which lead to blindness unless properly cared for

a study was made of 5,200 records from five representative eye clinics in New York including the Cornell Clinic, Manhattan Eye, Ear, and Throat hospital, Mount Sinai Hospital, New York Eye and Ear Hospital, and New York Post-graduate Hospital. To allow sufficient time to have elapsed for the clinic to have disposed satisfactorily of the cases, records of the patients who had visited the clinic for the first time at least one year previous to the date of inquiry were studied.

A lack of uniformity in records was one of the most salient defects discovered in the various clinics. Records revealed that a patient rarely made more than two visits. One hundred and three of the 193 cases presenting the selected eye conditions are recorded as attending clinic once, 22

attended twice, 38 attended from three to five times, 15 attended from five to ten times, 10 attended from 10 to 20 times, five attended over 20 times. Of the cases with these serious eye conditions which might bring on permanent blindness, 53.4 per cent attended the clinic only once. Only 15.5 per cent attended more than five times. The same point is brought out still more forcibly in the instances of certain especially serious diseases. This failure of the patients to return for further treatment is a stigma of failure on the part of the clinic in the opinion of the investigators. The records showed slight evidence of any attempt to insure proper care of the patient beyond the filling of prescriptions for drugs and glasses, and very little appreciation of the need to protect other members of society from infection.

On the basis of these findings the committee of ophthalmologists has adopted the following recommendations: (1) Systematic follow-up to insure continued treatment for at least the following types of cases should be instituted: optic atrophy; conjunctivitis (purulent); choroiditis (tubercular); corneal ulcers; glaucoma; iritis; interstitial keratitis; phlyctenular keratitis; tubercular keratitis; retrobulbar neuritis; sympathetic ophthalmia; papillitis; papilloedema; diabetic retinitis; pigmentosa retinitis; syphilitic retinitis; sarcoma of the choroid; trachoma; uveitis; (2) physicians should be responsible for seeing that the patient is informed of the nature of the trouble and the importance of treatment, and for deciding on what date the patient should return; (3) the social service department with such clerical assistance as is necessary should note the name of the patient whose return is desired and through the proper methods endeavor to secure his return at the date specified.

Seek More Care for Ohio's Feeble-minded

A proposal to amend the General Code of Ohio provides that the Director of Health "shall be appointed by the Public Health Council, by and with the approval of the Governor, to serve for a term of five years and until his successor is appointed and qualified." The present law provides for appointment of the state health director by the governor.

Another line along which public health legislation is foreshadowed in Ohio is the more adequate care of the feeble-minded.

The Play Street Prevents Child Accidents

Health Departments Can Reduce Traffic Casualties to Children

By ALBERT S. HYMAN, M.D., SUPERINTENDENT, MOUNT SINAI HOSPITAL, PHILADELPHIA, PA.

HOSPITAL administrators and executives are standing aghast at the appalling casualty lists which daily fill the accident wards of hospitals located in large cities. The grist of crippled and mutilated children, the toll of street accidents in busy congested districts has increased so rapidly that it would almost appear that the common diseases of childhood have been displaced from the wards of the general hospital by traffic casualties.

Records of hospitals situated in congested sections of large cities show invariably that a large percentage of traffic accidents occur to children. At Mount Sinai hospital, for example, 70 per cent of all street accidents occur to children under ten years of age. What is more dismaying, perhaps, is that 91 per cent of all deaths from street accidents occur in children. Hospitals similarly situated in other cities show approximately the same figures.

Safety-first campaigns apparently have not awakened the reaction which was anticipated and the slaughter of the streets increases. The toll of little lives sacrificed to the juggernaut of speed must force those interested in the preservation of life and safety to immediate action; for what availeth it to save one child from contagious disease only to have ten lost upon the streets of a busy city.

Solving the traffic casualty list is a movement which should be supported by all public health officials, yet it is disappointing to relate how little attention has been directed toward this menace to child life and how much time has been devoted to the remote causes of mortality among children.

A case is called to mind of a child carefully watched and treated for a nutritional disturbance by highly paid social workers. For two years this child had received the most scientific care and advice. Comes a day when the child is playing with his ball upon the street; a motor suddenly sounds its horn; the brakes grind—but it is too late. Another little life is snuffed out.

The death was reported to the public health agency that had carried the boy along for those two years and the

"More children die as a result of traffic accidents in Philadelphia every month than have died of rabies in the last ten years, yet the machinery for control of rabies is most elaborate and public health literature upon the subject is voluminous.

In contrast, how little have public health officials done to solve the death toll of city streets and how scanty is the literature upon it. . . . Prevention of traffic accidents in large cities should be just as much a part of any public health program as prevention of mosquitoes in rural communities."

only manifestation of concern at that agency was the act of removing his history card from the active files. On the same day, however, the death of another child under the agency's care from a nutritional disease caused the most profound consternation and the greatest activity among the clerks, social workers, and doctors. A special report was written and closer follow-up work was planned.

Two deaths had occurred; the one from a traffic accident and therefore without interest, the other from a nutritional disease and thus fraught with dire significance. For the first, there was no thought of future prevention; for the second, that it must not happen again! Yet the deaths from street accidents to children outnumber the deaths from nutritional diseases in that agency by 30 to 1!

The problem is a serious one. Not too much blame must be placed upon the motorist, although there are many that are prone to forget that little children have just as much (legal) right to play upon the public thoroughfares as the motorist has to ride upon them. Often the street is the only playground that a little one knows of.

On the other hand, the motorist has many a vexatious experience in passing through such thickly congested districts. Sounding a horn means very little to children who hear such warnings all day long and their indifference to the oncoming vehicle has caused alarm to many drivers; occasionally little imps prance with glee in front of the automobile, daring the driver to touch them. The human mechanism is not always perfectly

Underwood & Underwood
Seventy per cent of all street accidents and 91 per cent of all deaths from street accidents at Mt. Sinai Hospital, Philadelphia, occur in children. This boy narrowly escaped being one of the 70 per cent when he fell from his bicycle almost in front of an automobile.

Underwood & Underwood

New York's committee on recreation and playgrounds has closed certain streets in congested tenement districts to give children play space. Stanchions warn motorists to keep off.

coordinated; less so is the mechanism of steel and iron. A brake fails to hold, the steering gear does not respond quickly enough, and another little victim is added to the hospital's casualty list.

Whose Problem Is It?

It would appear to be a serious indictment against any public health program that does not take cognizance of this problem. More children die as a result of traffic accidents in Philadelphia every month than those that have died of rabies in the last ten years, yet the machinery for control of rabies is most elaborate and the public health literature upon the subject is voluminous. In contrast, how little have public health officials done in solving the death toll of city streets and how scanty is the literature upon it.

Many are the reasons given for the tardiness of public health departments in not recognizing the problem. The most common answer is that the prevention of traffic accidents is not clearly a phase of public health work, but rather that this lies within the police power of the city. Again, that public health programs are concerned only with prevention of disease. Some communities have not created a department of public safety, with the resultant confusion in placing the responsibilities of preventing such accidents, particularly in regard to children. Whatever has been responsible for the delay in recognizing the importance of traffic accidents, it should be immediately dissipated by recalling the statement made by Prof. Milton Rosenau of Harvard that

"public health and disease prevention mean the diminution of all causes of premature deaths." Prevention of traffic accidents in large cities should be just as much a part of any public health program as prevention of mosquitoes in rural communities.

Any method which will focus the thought of public health officials upon this problem and which will awaken the same enthusiasm for its solution as has been exhibited in the already conquered fields of typhoid and yellow fever prevention, will, it is certain, be greeted with jubilant relief from terrorized parents who daily watch the ghastly toll of their little ones beneath the wheels of an ever increasing vehicular traffic.

Of the pitifully few plans for the prevention of street accidents to children, the one most worthy of consideration is the playground street. The playground has ever been considered a legitimate part of public health work, and most cities possess fine playground systems. But such organized playgrounds are only accessible to the immediate neighborhood, so far as the small child is concerned. No parent is willing to send his child more than two blocks to a playground, and as a result the child is allowed to play on the street near his home.

The Playground Street

On the other hand, most municipal playgrounds are used by children over the age of ten. Let us recall at this point that 70 per cent of all street accidents occur in children under ten.

The conclusion seems to be obvious; if the playground is to be used as a means to prevent traffic accidents it must care for the child under ten, and not the child over this age. It means not an increase in the number of organized playgrounds, for no city can afford the space which would be required, but it means that the solution lies in bringing the playground to the child and not the child to the playground.

In matter of practice, a playground street is a city street which is blocked to traffic during certain hours of the day. Deliveries to houses within the street are permitted. The ends of the street are protected with iron stanchions. Streets where large numbers of children live and where there are

Underwood & Underwood

Side streets free from important traction lines afford a safe place for children to play and reduce accidents, New York police records show.

no important traction lines or fire runs are usually selected. Requests for the closing of streets usually originate from residents of the street, who in the City of New York, forward a petition to the Mayor's committee which was created for this purpose. An investigator then ascertains how many residents are willing to have the street closed, and how many are against closing it. He is governed by the majority.

New York is apparently the only large city to attempt this method of preventing street accidents among children. One hundred and thirty-two such playground streets have been created in New York; Philadelphia has had two such streets, and more are contemplated. The figures given by the New York police department

indicate that the reduction of such accidents has been remarkable, and the remedy has been so simple. Indeed, the simplicity of the playground streets is undoubtedly the reason why it was so difficult for it to be originally conceived, but having been conceived and proved successful, it should receive attention of all interested in this most recent of community hazards to child life, the juggernaut of speed upon the streets of our large cities. Let all public health officials and those devoted to children's welfare work bend all effort to induce the authorities in every large city to consider this or some other plan for reducing the terrific casualties resulting in death or permanent injury—day by day in every hospital in increasing numbers.

fronting on them. Many had small service alleys down the surface of which drainage from the 60,000 houses flowed. Today about fifteen miles only of such streets remain in this condition. Pavement on alleys which formerly were open sewers has increased from 5,490 square feet paved in 1915 to 130,976 in 1920.

Driving the pigs from the city of Philadelphia was another sanitary triumph of the commission. The first authentic census reported about forty thousand pigs within the city limits, thousands of them near schools, churches, and homes. Nearly all of these were fed on Philadelphia garbage carted through the streets. Vast areas were made foul by slovenly care given to the sties and by the disposal of muck therefrom. In sections of the "neck" cleanings were scraped from the pens into the swamp until it was filled above water level. Then the pens were moved further into the marshes and the process repeated until more swamp was filled, while over the old habitation a coating of cinders was spread, piles driven, and houses to hold families built. Today this has been stopped and it is doubtful whether forty pigs can be found within prescribed areas.

The slaughter house situation has also been remedied. Ten years ago a survey of small slaughter houses revealed illegal killing, cutting of animals that had died a natural death, slopping of freshly cut meat in offal

Housing and Municipal Health

MUNICIPAL sanitation is the foundation of personal health.

At least the Philadelphia Housing Association has found a direct correlation between the decrease in death rate and disease statistics and remedial sanitary conditions. Bernard J. Newman, director, says in his report:

"Housing and sanitary conditions have been far from satisfactory in Philadelphia but during the past decade great strides have been made in municipal sanitation. Without attributing an undue credit for the gains in public health to sanitary changes, the lowered death rate could not have been brought about had not municipal sanitation kept pace with other progress in the field of preventive and curative medicine."

Philadelphia is a healthier city in which to live now than it was a decade ago, states the report. In 1910 the annual deathrate was 17.29 per thousand population and the infant mortality rate was 135.28 deaths per thousand births. In 1921 the annual death rate was 12.55 and the infant mortality rate 77.8. This difference in deathrates means saving the lives of 8,846 persons who, if the 1910 rates prevailed, would have died in 1921. Such rates did not prevail because living conditions and other safeguards to public health have improved. Some of these improvements include not only the completion of the filtration plant and the distribution of a potable water to all sections of the city, the extension of the drainage system, better service in the storage and removal of insanitary wastes,

improved housing, extended sanitary inspection and similar potent factors in sanitary living, but also more spectacular changes.

Thus a decade ago Philadelphia had over 60,000 privy vaults. Since then over 45,000 of these fly-breeding and vermin-spreading cesspools have been cleaned, filled, and abandoned. Akin to this was the unsewered condition of built-up streets. At one time there were 135 miles of unsewered streets in the city with dwellings

A typical overcrowded room, housing five ship builders and a fourteen year old boy, discovered in the Philadelphia housing survey. Close proximity of sleepers and inadequate ventilation aid in spread of respiratory diseases.

Slovenly disposal of rubbish, garbage and ashes and defective outdoor water closet, constantly menacing health, have been banished in Philadelphia's cleanup campaign.

on the killing floor, tuberculous men handling and dressing beef. There were then 156 small abattoirs widely scattered and inadequately inspected; today over one hundred of these have

been eliminated and of the 47 that remain 12 kill under Federal supervision. A city abattoir is a sanitary need and one which will pay for itself, Mr. Newman points out.

Chicago Dental Society

WHAT is announced as the largest gathering of dentists in the history of the world met in Chicago during the fifty-ninth annual clinic and meeting of the Chicago Dental Society. Nearly ten thousand dentists were registered, representing every state in the Union as well as Canada, England, France, Belgium, and Australia.

The keynote of the conference—the conservation of health in dental practice—was the subject of the address

by Dr. Arthur D. Black. The connection between neglected teeth and systemic disease was fully established ten years ago, said Dr. Black, but the progress made toward removing the health menace of mouth infections is not sufficient to promise that it can ever be accomplished by present methods. All the dentists working all the time cannot keep pace with repair work. Much more consideration, therefore, must be given to preventive methods, especially the simple

and effective means of caring for the deciduous teeth.

As a comprehensive preventive program involves the professional supervision of the child from the age of one to eight years at three month intervals, and at six month intervals after that if all is well, some means of community service must be provided to care for the whole population. Announcement was made that this community need is about to be met in Chicago by the Chicago Dental Clinic, made possible through Pageant of Progress funds.

The administration of this service has been evolved from a preliminary survey made of existing services of this kind. It will include: (1) Dental hygienic instruction in all schools; (2) several dental centers where dental services of all kinds will be available; and (3) a limited number of isolated dental clinics available for outlying districts. The plan is to be developed so that within five years two hundred dental chairs will be devoted to caring for the teeth of poor children, and one hundred dental hygienists will be employed by the public schools.

Beginning has been made by the Northwestern University Clinic which is now operating fifteen chairs. The Dental Clinic would devote certain assigned space to senior students of every dental college in the city, where work would be done under proper supervision, thus making internships available for teaching purposes. The advantage to science—both general and special—in continuous records of all children, with radiographs of mouths, is apparent. Research on the basis of such records would register a much greater percentage of success than could obtain under other conditions.

Another phase of preventive dent-

Front elevation of building to be erected in Chicago to house a dental clinic of proportions heretofore not attempted. Under a plan fostered by the Chicago Dental Society it is expected that two hundred dental chairs and one hundred dental hygienists will be devoted to complete and continuous dental supervision of all school children in the city of Chicago.

istry was discussed by Dr. Vilray P. Blair of St. Louis. He stated that more than 50 per cent of cancer of the face and mouth can be eliminated in the pre-cancerous stage, and that the dentist's responsibility is considerable in enabling the early detection of mouth conditions in which chronic irritation is the precursor of cancer. The day is past when the dentist can safely ignore the health implications of bad mouth conditions. The cry is for more dentists, for more and better dental surgeons, for wider prophylaxis, and for that trained, alert ob-

servation on which early diagnosis of complicating conditions must depend. "If every patient having a cancerous degeneration were treated in time," Dr. Blair said, "50 to 75 per cent of cancers of the mouth could be cured without risk of mutilation."

The legislation that is to be proposed to the Illinois legislature was discussed by a joint session of the committee on legislation of the Illinois Dental Association. The tentative program includes a general revision of the dental act, and a law for licensing "dental hygienists."

ranged by tying a cord across and draping sheets over it. Such an arrangement insures privacy where each child can be undressed and examined one at a time. The younger children are divested of their upper clothing and covered with large turkish towels. When it is necessary for them to remove their shoes, and this is always done when they are weighed and measured, they are furnished with socks to slip on over their stockings. Older girls simply have their clothing loosened sufficiently for the physician to examine their hearts and lungs. Such an examination is not complete, but is all that can be attempted by the present.

Following the examination, parents of the children are notified by card of any defects found in their children and are urged to have these defects corrected. A congratulatory card is sent to those parents whose children are free from defects. In about six weeks or two months, the nurse again visits the school to find out how many defects have been corrected. Where no attempt has been made at correction, the nurse visits the home and emphasizes the importance of remedying the defects, and urges the parents to get the advice and assistance of their family physician. In needy cases, the nurse and teacher cooperate in trying to obtain free medical attention.

A chart with the name of each child is placed in the school room. The chart is divided into headings: Eyes, ears, nose, throat, mouth, skin, chest, nutrition, orthopedic, mental, vaccination. Blank spaces are left for additional notations. Any child found perfect in regard to these different headings receives a gold star for each perfection. A vacancy on the chart shows a defect to be corrected. The object of this score card is to bring a visible reminder to the child to get a gold star after his name under each heading. In consequence of this score card, children are bringing intensified effort on home folks to have their defects corrected, in order to have stars appear under each heading of their chart. This it is believed will lessen the number of visits of the nurse to the home in follow-up work and will enlist the cooperation of the child and his parents.

A few results of medical inspection during last school year are mentioned in order to show the great need for it in this state. Of 15,098 children examined, only 1,164 were found free from defects. There were 1,191 cases of defective vision, and 191 cases of other eye conditions; 5,038 children

Delaware's School Inspection

MEDICAL inspection of rural school children of Delaware has been made possible through the cooperative efforts of the Medical Society of Delaware, the Delaware State Dental Society, the Delaware School Auxiliary Association, American Red Cross, state board of education, and the child welfare commission of Delaware. During the school year of 1921-22, the Delaware School Auxiliary Association furnished funds amounting to \$4,300, which was used to pay for medical services and printing, and \$6,700 which was used for the operation of the dental unit. The American Red Cross furnished nursing service for the schools of New Castle County, exclusive of the city of Wilmington, with the exception of Blackbird Hundred. Blackbird Hundred and the other two counties of the state, Kent and Sussex, were examined by nurses of the child welfare commission, and the director Dr. William J. French, served as state director of medical inspection for the state department of public instruction up to the time of his resignation and leaving Delaware just a month ago. The state medical society, through a committee of three, nominated the physicians who made the examinations and supervised the work from a professional point of view. The dental society, also through a committee of three, supervised the work of the dental unit.

The Red Cross has this year ceased giving nursing service for the medical inspection of school children, and the entire burden of the nursing service falls upon the child welfare commission. The Delaware School Auxiliary Association is giving \$3,000 for medical services, printing, etc. When this sum is exhausted, the child welfare commission will assume all financial obligations. The dental unit,

however, will be supported this year by the Delaware School Auxiliary Association, which has contributed \$7,200 for this work. It is not expected that this sum will be contributed after the school year 1922-23.

The nurses endeavor to examine first those schools which are situated furthest from the main highways and good roads and to leave for bad weather period the schools which are more easily accessible. The general method of procedure is for the nurse, after arranging a date for the examination of a school with the local board, to visit the school in the morning, taking with her equipment needed, such as scales, measuring tapes, Snellen's test charts, tongue depressors, sheets, towels. After obtaining certain routine information about the child, such as the name, address, which is entered on a physical examination form and filed in the school, she proceeds to weigh and measure him, examine his skin, hair and teeth, ask as to use of toothbrush, and make simple tests of sight and hearing. These observations are likewise entered upon the examination form. The same afternoon, the physician visits the school and with the assistance of the nurse makes a thorough physical examination consisting of investigation as to the following:

Defects auditory apparatus; defects visual apparatus; nasal defects; throat affections; heart disease; pulmonary disease; mental and nervous disease; orthopedic disease; speech defects; spinal defects; skin and scalp conditions; nutrition; mentality; other defects or deformities.

Great care and circumspection has been used in making these examinations. Many of the schools are small, sometimes only one room, and it is necessary to use one end or corner as an examination room. This is ar-

had enlarged tonsils, and 3,276 children were undernourished.

Due to various epidemics among the school children and also to the fact that several of our nurses contracted influenza last winter, medical inspection of all the rural schools was not completed. This year we expect to be able to complete inspection of all the schools, and this involves, according to our estimation, the medical examination of about 25,000 children.

The Dental Unit has already been mentioned. This consists of three dental hygienists who have the use of a truck for transporting equipment to the various schools. The same method of approach to the schools is used as with the medical examination. The hygienists give a simple talk to the children, demonstrate the use of the toothbrush, have a toothbrush drill, and then set up the chairs and proceed to examine their teeth, giving prophylactic treatment. Where trouble is found to exist, cards are sent to the parents urging them to send their children to their family dentist.

Of 2,023 pupils examined and treated last year, 1,888 had defective mouths, leaving only 135 or 6.67 per cent with perfect mouths.

The unit is truly popular, not only with the children, who sometimes fight to be "next," but with the school principals also. Many requests are made for the unit, and it is unfortunate that only a small number of the schools of the state can be visited by the dental hygienists each year. The parents also appreciate the services of the dental unit and are sending their children to the dentist as a result.

The state department of public instruction has backed the work of medical inspection and of the dental unit in every way, and is thoroughly in accord with the child welfare commission that this work should be made a permanent part of the educational program.

It is hoped that this session of the state legislature will see the passing of a law to amalgamate the various health agencies now operating in Delaware. At the present time, however, the several health agencies operate as separate units.

International Conference on Sera

The second general conference for the standardization of sera and serological tests, held from November 20 to 26 at the Pasteur Institute in Paris, under the chairmanship of Prof. Dr. Th. Hadsen, director of the

Danish State Serum Institute and president of the League Health Committee, was attended by representatives of the chief sero-therapeutical and bacteriological institutes of Austria, Belgium, Denmark, France, Germany, Great Britain, Japan, Poland, Roumania, Russia, Switzerland, and the United States.

The conference confirmed the agreement on the standardization of antidiphtheria and anti-tetanus serum units arrived at in the Geneva conference of September, and collated the results of the research work undertaken on anti-meningococcus, anti-pneumococcus, and anti-dysentery sera, and on the sero-diagnosis of syphilis.

Ever since the method of immunization and cure by serum injections was discovered great practical difficulties have been met with, owing to the effect that the methods for measuring and testing the strength of sera had been built up in different ways, often on entirely different principles, in the bacteriological laboratories of different countries, sometimes even in those of the same country.

Introducing uniformity into the methods of different laboratories would allow of a fuller exploitation for the purposes of curative and preventive medicine. But although this was realized even before the war, all attempts to overcome the difficulty had broken down on the question of securing sufficiently prolonged and close cooperation among a sufficiently large number of laboratories and institutes from different countries.

For this reason the matter was taken up by the League Health Organization which seemed peculiarly suitable for uniting and co-ordinating the efforts of a great many separate national institutes. It was at the instigation of the League Health Organization that the first conference was held in London in December, 1921, and drew up the program of joint work that has been carried a long step further at the Paris conference just concluded.

The Present Crisis in Russia

The most remarkable fact about Professor Tarashevich's report on Epidemics in Russia since 1912, appearing in the 5th or October number of the *Epidemiological Health Bulletin*, is the author's statement that "Russia may consider herself fortunate if she emerges from the present crisis with the loss of only 20 to 25 per cent of her population." The crisis is described as not only political

and economic but biological, because of the disturbances which it has caused in the whole domain of human physiology and pathology. Thus, not only are epidemic diseases such as typhus, relapsing fever, intestinal infection, malaria and scurvy, which have always existed in Russia, aggravated both in prevalence and virulence, but nearly all other epidemic infectious diseases have been greatly increased, hitherto unknown diseases have been observed, and there has been a quasi-epidemic extension of many non-contagious diseases, such as disorders of the nervous system and the heart, general functional disorders, etc. Behind all stands the famine, which not only causes millions of deaths in itself, but predisposes whole populations to sickness and death by disease. The very stamina and physical standards of the Russian race, the biological basis of Russian society, have been pulled down by the events of the past few years.

It is becoming more and more necessary that Europe should aid Russia. If such aid is not forthcoming Russia, thanks to her natural resources, will ultimately triumph over her present troubles, but after a much longer time and at the cost of countless lives.

Bundeson Appoints Health Advisory Staff

Dr. Herman N. Bundeson, health commissioner of Chicago, has appointed the following advisory staff: laboratory advisory committee, Dr. Ludvig Hektoen, director of the McCormick Institute for Infectious Diseases; Arthur I. Kendal, Ph.D., dean of Northwestern University Medical School, and Dr. David J. Davis, head of the department of bacteriology of the University of Illinois. On the consulting staff of pediatricians are: Drs. Julius H. Hess, University of Illinois; Clifford G. Grulee, professor of pediatrics, Rush Medical College, and Isaac A. Abt, Northwestern University Medical School. Departmental advisers on prenatal care are: Drs. Joseph B. DeLee, head of the Chicago Lying-in Hospital and professor of obstetrics, Northwestern University Medical School, and Davis S. Hillis, associate of Dr. DeLee. Dr. Louis E. Schmidt, professor of genito-urinary surgery, Northwestern University Medical School, is departmental adviser on venereal disease; Dr. Walter H. O. Hoffman, attending physician of the Children's Memorial Hospital, is lecturer and adviser on infant welfare.

Superstition As Affecting Disease Prevention

By A. LEVINSON, M.D., CHICAGO.

CONTROL of communicable diseases involves many and varied activities on the part of the health department and the closest co-operation between the health department and practising physician. Even when all the essential health machinery is perfect, however, control will fail in the absence of a knowledge on the part of physicians and nurses of the notions that may be current in regard to the communication and treatment of contagious disease. The control of communicable diseases by measures which cut off contact fails in a neighborhood where the opinion is current that everyone must at some time or another inevitably contract some contagious disease. It is by no means uncommon for mothers to expose their children to measles "to get it over with." In one of my patients this practice resulted in death from secondary meningitis, and in two other cases broncho-pneumonia was the result. Six children were affected in the family which disregarded orders for the isolation of the first patient and neighboring children were brought in to share the infection.

Such practices are less marked in scarlet fever, meningitis, and whooping cough yet it is by no means rare to find a mother who deliberately exposes her child to whooping cough in utter disregard of the seriousness of the infection and the physical handicaps that frequently follow in its train.

Curious notions connected with the "no bath" idea often carry potential harm. Many women cling to the notion that in the case of chicken pox the skin should never be wet, the belief probably being carried over from the idea that chicken pox is a wind pox and that, therefore, no wind or water must come in contact with the body. The ill effects of leaving the skin without water for ten or twelve days are apparent. The sick child must be regularly bathed both in the interest of cleanliness and to afford a simple means of reducing high bodily temperature. In order to appease a prejudiced mother or grandmother, however, the nurse may need to refrain from giving the child a tub bath and to use a sponge bath only. A superstition that probably does no harm but certainly does no good is the supposed danger of bathing any child with scarlet fever or measles.

This superstition might, in rare instances, be of some service in view of the fact that if a child is not bathed his heart is not over-taxed and a possible myocarditis may thus be prevented, but even here the "no bath" idea is carried to the extreme of not allowing any water to come in contact with the skin.

The "no light and no air" notion of measles is so prevalent that children are often thereby rendered the more susceptible to pneumonia. It is a common experience to see otherwise intelligent parents confine children to hot rooms during the first few days of measles, no ray of sunlight and no breath of fresh air being allowed to enter the room. Darkening the room during measles assumes that conjunctivitis, one of the cardinal symptoms of the early stages of the disease may be aggravated by exposure to light. On the contrary, light need not be considered injurious. Much worse than excluding light is the danger of excluding air. Fresh air in circulation is necessary for children under all circumstances and it is highly unfortunate that children affected with measles are so often kept in rooms with a temperature of 80 to 85 degrees and are covered with quilts and spreads for additional warmth. Only recently the mother of one of my patients not only excluded the air from the sick room but heated the stove and put an onion poultice on the child's chest, back and front, so as to make sure that the child would be kept warm. The broncho-pneumonia that ensued was a natural result.

Another practice with serious consequences is the treatment of whooping cough by taking the little patient to the gas plant. The disease is supposed to subside when the child is put in an atmosphere of carbon monoxid. It is tragic to know that people in civilized communities will, under any circumstances, carry their children to a gas plant in order to saturate their lungs with carbon monoxid. Rich people even go to the length of introducing coal into the apartment and lighting it so that coal gas will emanate. Many deaths from broncho-pneumonia following whooping cough have resulted from this mistaken coal gas treatment.

It is easy to see how this superstition originated. A child exposed to carbon monoxid is suffocated to a

greater or less degree, the suffocation acting as a sedative for the paroxysm or whoop. It is not commonly understood, however, that suffocation may well produce a lasting and highly dangerous effect.

A less radical but quite an irrational treatment is the lighting of creosote lamps in the patient's room so as to suppress the paroxysm, the fact being overlooked that the sick child is thereby subjected to additional headache and nausea resulting from the treatment.

Another extreme but popular treatment of whooping cough is the method of taking the little patients to the lake. Cold air, though less harmful than coal gas, predisposes patients with whooping cough to pneumonia and it is folly to keep the child near the lake for more than a few minutes at a time. The good effect is possibly due to the temporary suppression of the whoop by the sedative action of the cold air but prolonged exposure does more harm than good.

Another opinion held by some physicians as well as by the laity which needs to be counteracted by educational methods and that is that patients with contagious diseases should be starved or kept on liquid diet. Modern research has amply proved that patients suffering from contagious diseases fare better on semi-solid than on liquid diet. During the recent influenza epidemic many a child developed acidosis because of the starvation diet imposed. It was fortunate that some children were given large quantities of medicine which contained a great deal of syrup, the carbohydrate in the syrup in such cases serving to sustain the child's life. A dietary not exclusively carbohydrate would have been better.

Another more or less common prejudice is expressed by some of the older generation who say that milk produces fever, a conclusion probably reached because febrile patients often vomit milk. It is true that patients with fever tolerate milk less than thick food and, as patients tire of an exclusive milk diet this fact can be utilized in the treatment of contagious diseases as it permits the feeding of patients on a soft instead of a liquid diet.

The eradication of superstition will contribute much toward prevention and cure.

Digest of Sanitary and Hygienic Advance

ARIZA, quoted in the tenth Annual Report of the Medical Department of the United Fruit Company, makes the following interesting clinical observations as the result of 304 cases of alastrim-small-pox studied by him:—

(1) It is milder in children than in adults.

(2) The eruption in many cases is very abundant and confluent, lacking the severe symptoms of confluent variola vera.

(3) Secondary fever is absent in most of the cases, even those of a confluent nature; and, if present, is of a very mild type.

(4) The stage of invasion is absolutely similar to that of variola vera, with high fever, headache, backache and vomiting.

(5) The stage of eruption is quite different from variola vera. I have not been able to observe the different rashes so frequently seen in variola vera before the papular stage.

(6) The papular stage is a protracted one, and it takes a much longer time for the papules to become vesicles; and, in the mild cases, only the apex becomes vesicular. The papule come out in crops, and gradually cover the whole surface of the skin.

(7) The crusts are not so thick as those of variola vera, and when they fall off do not leave any pitting, but a good deal of discoloration.

Scrotal Cancer

Southam and Wilson (*B.M.J.*, 3229, November 18, 1922, p. 971) in a study of 141 cases of epithelioma of the scrotum made by them at the Manchester Royal Infirmary, note that while the disease is one which is generally regarded as occurring chiefly among chimney-sweeps, there was only one member of the industry in the series on which they report. Their cases were divided according to occupation as follows: Mule-spinners, 69; tar and paraffin workers, 22; sweeps, 1; various occupations, 38; not stated, 11; total, 141.

The average age of these patients was fifty-one years. The authors conclude that while epithelioma of the scrotum is rare among the chimney-sweeps in South Lancashire, in that district the disease is most frequently met with in mule-spinners in the cotton mills, chronic irritation resulting from friction and contact with oil being the etiological factor. The piecing of broken threads on the spindle necessitates leaning with the left groin and scrotum against an oil-covered bar. This labor is performed in a warm humid atmosphere and the workers perspire freely. The trousers

are always oil-soaked at the level of the upper thigh and lower abdomen and much itching of the parts is apt to follow. Lack of scrupulous cleanliness seems to be an additional factor. The disease is similar in general features to other forms of cutaneous cancer and is equally malignant.

Hereditary Syphilis

Leredde speaking before the Physicians Society of Paris at its meeting of June 9, 1922 (*Le Prog. méd.*, 27, July 8, 1922, p. 324) on the treatment of hereditary syphilis expressed the thought that most syphilitic infants die because the disease remains unrecognized until it is difficult to cure. He believes that the classical method of mercurial inunctions is barbarous and that the disease should be treated in exactly the same manner as it is in the adult with adequate laboratory control of the results.

Vaccination in Switzerland

In the 1921 report of the Swiss Federal Service of Public Hygiene data are given of 398 cases of small-pox. Of this group 359, or 90.18 per cent were in the non-vaccinated; 16, or 4.03 per cent, in the re-vaccinated and 23, or 5.78 per cent, in those reported as having been successfully vaccinated. Not a single death occurred in the vaccinated group.

Typhoid Fever Carriers

Dittmar in a communication to the Royal Society of Medicine on "Some Outbreaks of Enteric Fever due to Carriers of Infection," (*Proc. Roy. Soc. Med.*, xvi, 1, November, 1922) comments on the difficulties surrounding the administrative treatment of carriers of infection. There is adequate power in the public health laws and regulations of Scotland to deal with a person adjudged to be a carrier of an infectious disease in the same manner as if he actually suffered from the disease itself, but before a person may be deemed a carrier he must be certified as such by a medical officer of health and another registered medical practitioner, such certificate being effective for a period not to exceed three months. Further examinations may be made at any time after the date of the certificate and the carrier may demand to be re-examined during the currency of the certificate on giving the medical officer of health

not less than forty-eight hours notice in writing. Carriers have the right of appeal.

Dittmar is of the opinion that while the liberty of the carrier should be safeguarded, the period of the validity of the certificates is too short in the case of typhoid carriers, who may remain infectious for a period of many years. He therefore recommends that after the expiration of the first certificate the period for re-certification should be yearly. The most important disability of the carrier, most of whom are women, is their inability to earn a living as housekeepers, cooks, and dairy-workers. In the interest of others, typhoid fever carriers must not continue to do work which involves the preparation of food. The author believes that if they must change their means of livelihood in the public interest, the charge of this should fall on the public purse. Each case would have to be judged on its merits and the individual circumstances and possibilities carefully investigated by the health officer and if he could certify after such an investigation that the carrier could not earn a living at another form of occupation, a disability pension should be paid by the state. Of course, such a pension would lapse should subsequent examination prove that the person had ceased to be a carrier.

Immunized Dogs Need No Muzzles

The California State Board of Health is to be congratulated on the "sweet reasonableness" of its amendment to its regulations for the control of rabies. Under the new ruling dogs which have been immunized or vaccinated with anti-rabies virus are exempted from quarantine or muzzling. A numbered tag showing the year issued and giving information that the dog wearing the same has been immunized is issued to the dog owner, who is required to attach it firmly to the dog's collar. The collar must be worn at all times except when the dog is in strict confinement.

Widal Test

A. G. Shera concludes (*B. M. J.*, 3231, December 2, 1922, p. 1077) from a small number of tests "that a positive Widal reaction in the un inoculated subject, even some four or five years after inoculation, is of no diagnostic value whatever in typhoid

fever and is of very doubtful value in paratyphoid fevers unless of very high titer. But this in no way detracts from the value of the reaction in the non-inoculated.

Isolation of *B. Tuberculosis* by the Use of Glycerin

As a means of isolating acid-fast bacilli from contaminated material Twort (*Lancet*, ii, 5180, December 9, 1922, p. 1221) finds glycerin extremely useful; its efficacy infinitely superior to the chemicals which have been used for this purpose. The method consists in placing a large platinum loopful of sputum or other material from which acid-fast bacilli are to be isolated, into tubes containing 1 c.c. of pure glycerin, 75 per cent, 50 per cent, and 25 per cent in normal saline. After twenty-four hours at room temperature these are cultured on 4 per cent glycerin egg medium, or petroff's medium. If contaminations are numerous further cultures are made on the third day. Sometimes all contamination is destroyed in twenty-four hours, usually not. It may be necessary to resort to a third culture after a week.

Specimens in which *B. tuberculosis* have been demonstrated microscopically, if left sufficiently long, have uniformly given pure cultures. The exact percentage of glycerin and temperature best suited for isolation have not yet been determined. It also remains to be shown if it is possible to isolate when the bacilli are very scarce and in highly contaminated material, such as milk or stools.

The Larvacide Developed by Panama Health Department

The chief health officer of the Panama Canal in his annual report for the calendar year 1921 expresses the belief that the Panama Canal "larvacide" developed some years ago by the Health Department of the Panama Canal has won a reputation in the opinions of anti-malaria workers as an effective agent for destroying mosquito larvae. It consists of a crude carbolic acid-resin soap solution which readily emulsifies in water and is a potent destroyer of larvae in highly dilute proportions. It is especially valuable in its quick action on larvae, its ease of application, and because of the fact that it diffuses rapidly and penetrates into small pockets of water or where vegetation and debris are abundant. It is also much used where black oil cannot be applied because of the unsightliness or other damage it causes. When it was first

developed, the cost of making was relatively low, about 14 cents per gallon. The present cost is about 62 cents per gallon.

Of late years the principle use of "larvacide" has been as a diluent for black oil (crude petroleum with an asphalt base) to enable it to flow freely through the piping and nozzles of spray pumps. It was noticed that, although the mixture flowed with ease, when it was applied to the water, the oil failed to spread into a film but remained floating in the form of globules, requiring the application of a large amount to cover thoroughly the water with oil. The "larvacide" diffused and after some hours, or even days, the oil showed a tendency to film. Experiments were undertaken to determine the cause of non-filming and to discover a cheaper more effective diluent. It was soon noted that any soapy substance impaired or practically destroyed the filming tendency of oils and, as larvacide is a resin soap solution of carbolic acid, its deterrent action on filming could not be overcome. Kerosene and other lighter oils were tried but were not satisfactory because of low filming power or excessive cost. Crude petroleum (fuel oil) alone appeared to have the best covering power when applied to water and the solution of the problem seemed to lie solely in devising means of applying the oil economically and effectively. This was done. By heating the oil and spraying while it was hot, a perfect film formed wherever vegetation or debris did not obstruct. In grass-grown shallows when sprayed at a high angle to allow the oily mist to fall vertically a covering of oil was obtained. Less oil is used by this method and it has been found needless to cut grass around the margins of small lakes, since the application of oil by this method has proved satisfactory. A saving of about eight thousand dollars per year will result from the adoption of the hot-oil spray. The chief use of "larvacide" by the Health Department by the Panama Canal is as a fly destroyer and repellent.

Simple Method for Collection of Specimens

A simple method for the collection of specimens for the examination of suspected typhoid carriers is described by Klotz (*J. A. M. A.*, lxxix, 23, Dec. 2, 1922, p. 1931). When a large number of persons are to be examined, procedure is simplified by the use of a large paper container about 6½ inches square and 3½ inches deep,

known as a "hemorrhage cup." These cups are made and sold by some of the manufacturers of burnable sputum cups. Stools are evacuated directly into the paper cups and a small thoroughly mixed portion transferred with a spatula to a tin pill-box which is sent to the laboratory for examination. Such a method prevents contamination of negative samples and prevents serious error in the findings for the group.

Carbon Tetrachlorid

The administration of carbon tetrachlorid to more than twenty thousand persons in the colony of Fiji has been reported by S. M. Lambert (*J. A. M. A.*, lxxix, 25, December 16, 1922, p. 2035). The dose given was 0.2 c.c. (3 minims) from one year of age up to the age of 15, when the adult dose of from 3 to 4 c.c. (from 45 to 60 minims) is reached. The conclusions are that this drug is a vermifuge and vermicide of great potency, giving little discomfort to the patient; and that it permits rapid treatment at a low cost of vast populations suffering from hookworm disease. Reexamination of some eight hundred treated patients indicated that the infection rate of the community was lowered from 100 per cent to less than 9 per cent.

The Preservation of Milk and Foods by the Use of Nitrol

Bart (*Archiv f. Hygiene*, xci, 1922, p. 1) reports tests on the antiseptic and disinfectant powers of N₂O. When applied under pressure of thirty-five atmospheres, this gas proves highly efficient as a sterilizing agent and the author believes that it may have a field in the preservation of milk and other perishable foods. The advantage of such a process as compared with simple heat treatment do not seem obvious.

Atypically Staining Tuberculosis-like Bacilli

European laboratory workers have been much interested of late in the bacterial types described by Much which are not acid-fast but which he and others believe to be strains of tubercle bacilli. Peter (*Beit. z. Klin. der Tuberculose*, lii, 1922, p. 70) presents data to prove that these atypical forms are relatively much more common in early cases than in late cases and in cases with favorable as compared with unfavorable prognosis. He believes the relative proportion of the two forms is determined by the selec-

tive forces operating in the struggle between invader and host. The whole theory seems a trifle fantastic, but the results presented are sufficiently suggestive to warrant repeating the work.

Treatment of Trypanosomiasis

Experiments are being actively carried forward, both in France and in Germany, on the preparation of effective drugs for the destruction of trypanosomes in the body. Navarro Martin and Stefanopaulo (*Annales de l'Institut Pasteur*, xxvi, 1922, p. 619) have obtained promising results with aminophenol-arsenate of soda.

The Tuberculosis Dispensary a World-wide Institution

Sir Robert Philip, President of the Section of Tuberculosis of the British Medical Association (*B. M. J.* 325, October 21, 1922, p. 733) in his introductory remarks at the 1922 annual meeting at Glasgow, made a comparison between present day tuberculosis conditions and those of 1888 when the Association last met in Glasgow. At that time the tuberculosis bacillus had been known for six years yet the first tuberculosis dispensary had just been established and the tuberculosis sanatorium was only beginning to be spoken of. Since that time the bacillus has been the subject of vast scientific investigations; the tuberculosis dispensary has become a world-wide accepted institution; instrumentalities for the recognition and the cure of the disease have been created everywhere; in Great Britain the necessity of linking the various institutions has been officially recognized; tuberculosis schemes have been established by statute; the disease now occupies a place in the group of the infections and notification of all its forms is compulsory. During 1921 in England and Wales, the number of such notifications amounted to 71,702 and in Scotland to 12,524. On June 1st, 1922 the tuberculosis schemes in England and Wales included 381 tuberculosis officers, 441 tuberculosis dispensaries, 84 visiting stations and 20,395 beds in sanatoriums and hospitals, with 2,664 additional beds in preparation. At the same date in Scotland, there were 80 tuberculosis officers, 29 tuberculosis dispensaries and 3,558 beds. The drop in the tuberculosis death rate has been remarkable and reassuring. During the period from 1881 to 1890 the average number of deaths from tuberculosis in England was 66,526, i.e., 242 per 100,000; in 1919 the number

of deaths was 46,310 or 126 per 100,000; in Scotland the corresponding figures are, 1881-90, 10,645 deaths or a rate of 276 per 100,000 and for 1919, 6,326 deaths, a rate of 129 per 100,000.

Results of Anti-Malarial Operations

The results of the anti-malarial operations in the Panama Canal Zone are well shown by the fact that, while in 1881 the malaria death rate was estimated at over 20 per thousand of the population, and in 1906 it was 9.49 per thousand, by 1920 it was reduced to 0.08 per thousand for the Canal Zone and the terminal cities of Panama and Colon. In the employees alone, the rate in 1906 was 7.45 per thousand and in 1921, it was zero.

The Prevalence of Syphilis in Denmark

The frequency with which syphilis may be demonstrated clinically and at necropsy is shown by the data collected by Melchior (*Hospitalstidende May 12, '22*, p. 106 and *B. M. J.* 3210, July 8, '22) in the course of a series of studies of 5,865 bodies examined at the Communal Hospital in Copenhagen from 1914 to 1920. In 4,717 of persons over fifteen years of age, there were 358 or 7.6 per cent with anamnestic, clinical, or post-mortem evidence of syphilis. Of these 69 per cent were males. The effect of the disease on longevity is shown by the fact that 65.4 per cent of the syphilitics died between the ages of thirty and sixty years, whereas only 46 per cent of all patients died between these ages. Only 25.1 per cent of the syphilitics died after the age of sixty and only 7.2 per cent after the age of seventy, while in corresponding age groups in the general body of patients, the percentages were 44 per cent and 22.5 per cent respectively. A definite history of infection was obtained in 54 per cent of the syphilitics and the date of infection in 50 per cent. At necropsy, syphilitic changes were found in 69.3 per cent, the highest percentages being found in the upper age groups.

May Bank Notes Transmit Itch?

The itch for money has long been recognized as a definite entity but itch from money and the possibility of its acting as the disseminating agent of true itch has received scant consid-

eration. The Director of Medical Research for the Gold Coast in the report for the Accra Laboratory for 1920 sets forth the results of the examination of some shilling notes which well deserved the name of "filthy lucre." Ten of the notes, chosen at random, were soaked in sterile salt normal solution in a sterile dish for half an hour, brushed with a sterile brush and removed. The remaining fluid was examined microscopically, tested for *B. coli*, plated on agar and planted on various culture media, centrifuged and the deposit examined microscopically. *B. coli* was not demonstrated. There was no evidence of faecal contamination. As might be expected, vast numbers of bacteria, yeasts and moulds were found. The deposit contained sand and grit, food material, pollens and not a few sarcoptid mites and eggs. The mites were alive and active.

Human Plague Carriers

Wu Lien Teh (*Jour. of Hyg.* xxi, 1, June, 1923, p. 62, et seq) in an epidemiological description of plague in the Orient with special reference to the Manchurian outbreaks, raises some very interesting speculations by his report of human plague carriers. The discovery of the first authentic cases was accidentally made among a collection of contacts. A motor-car driver was admitted to a hospital with eighteen other contacts from an inn in which there had been a plague death and the following day complained of headache. He was found to have a slight elevation of temperature and his sputum, which was apparently normal, contained bacilli suspicious of plague. Cultures and inoculations into guinea pigs demonstrated the bacillus pestis. On the sixth day after admission, the patient, who had remained perfectly well, except for the slight headache and fever just mentioned, was carefully re-examined. Swabs taken from the tonsils were positive for the plague bacillus by both cultural and guinea pig tests. Another case was that of an apparently normal contact whose sputum was also positive. Teh wisely observes that "it is premature to say how far the question of carriers influences the course of a pneumonic plague epidemic." It is his belief that pneumonic plague epidemics arise as a secondary manifestation of bubonic plague and that the prevalence of purely septicemic cases towards the end of the epidemic is significant as a probable explanation of its decline and termination. He states

that rooms where patients have died of pneumonic plague are not particularly dangerous, in four instances recorded, sick patients travelling in railway carriages did not infect their fellow passengers. Alcohol, he believes, is the surest way of sterilizing the hands and gloves in pneumonic plague work, since other disinfectants and antiseptics, even in strengths above those usually employed, have very little effect upon plague sputum. The mask is the principal means of personal protection against pneumonic plague. The problem of successful vaccination against pneumonic plague still awaits solution.

Improved Technic for the Identification of Diphtheria Bacilli

Pergola (*Bol. della R. Acad. di Roma*, 1920-21, *Anal. by L'Igiene Mod.*, xv, 1, Jan. '22, p. 23 and *Bul. Office Internat. d'Hyg. Pub.*, xiv, 5, p. 567, May '22) proposes to substitute for Loeffler's serum and Conradi and

Troch's medium, a new medium of his own composition, containing tellurite of potassium. He uses four preparations, solidified by gelatin, or substances which grow the diphtheria bacillus, or with egg yolk, or with blood serum. Selenite cannot be used in place of tellurite. These media are very selective and give very satisfactory results since they restrain well the growth of other organisms and they permit the very easy identification of the diphtheria colonies by microscopical examination, even though they may not be numerous and scattered among numerous colonies of other species. The four media of Pergola do not present the hindrances of other media, for example that of the difficulty which is often encountered in the process of sterilization. The author gives directions for the economical and ready preparation of the media and points out the necessity of inoculating the plates by striae in order to obtain good isolation of the colonies.

and Miss Foley retained as the directing genius of the association.

Summer Nursing Courses

The department of preventive medicine and public health of the University of Minnesota offers for public health nurses, a six weeks course in maternity and infant hygiene, in cooperation with the division of child hygiene of the State Board of Health, the Visiting Nurse Association of Minneapolis, and the Infant Welfare Society of Minneapolis. The summer session is from June 26 to August 3, 1923.

The course consists of the following subjects: principles of public health nursing, maternity and child hygiene and supervised field practice in maternity and infant welfare.

In addition to these courses, opportunity is given to elect other subjects offered by other departments during the regular summer session of the university. Those interested in these courses should send to the Registrar, University of Minnesota, for a bulletin of the summer session.

The courses in maternity and infant hygiene are open to all public health nurses who are considered qualified to pursue this type of work to advantage, but college credit will only be given when college entrance requirements have been fulfilled.

Reduction in Health Appropriations

An unfortunate tendency to carry municipal economy into public health is shown in the reduced health department appropriations in Cincinnati. The appropriation of \$135,000 is twenty thousand dollars less than the authorization for this year. The per capita cost for health conservation last year was 40 cents. The per capita cost this year is 33 cents, the lowest of all cities in its class. This reduction has compelled the sacrifice of eleven full-time and ten part-time employees, and the suspension of publication of the *Sanitary Bulletin*. Such action seems particularly regrettable in view of the conservative estimate of the Committee on Municipal Health Department Practice of the American Public Health Association that an appropriation of about \$1.12 per capita is essential for the discharge of the fundamental responsibilities of the municipal health department, even excluding all money spent for public health nursing and the maintenance of contagious disease hospitals.

Chicago Visiting Nurses

THE Chicago Visiting Nurse Association on the occasion of its thirty-third annual conference presented a case for nursing needs and humanitarian values in nursing service that merits the consideration of health bodies everywhere. Organized in 1899 with only one nurse, its personnel increased to four the first year. The present staff numbers 107, and the supplementary services, created as the need developed, chronologically represent a fair index to the development of public health nursing. The first industrial section was created in 1903. The Chicago Milk Commission, formed in 1909, split off to form the Infant Welfare Association which has done such comprehensive work; and the highly specialized service of the division that has to do with reclaiming those afflicted with infantile paralysis has done path-finding work among crippled children.

Public approval kept pace with the broad vision of the directors of the association and the first endowment, received in 1899, has by a process of accretion grown to the significant total of \$851,000, a sum not commensurate with the nursing needs of an urban community like Chicago, but sufficient to stabilize the work and subject to gradual increase. The stability of the organization is further attested by the small change in per-

sonnel. Of the total of 155 persons who have served on the directorate, 113 are still active. Medals for five to thirty-three years of service were on this occasion awarded to something less than fifty nurses and members.

The address of the director, Miss Edna L. Foley, brought out the increase of effectiveness through affiliation with other social agencies, for it is not with skilful hands alone that the nurse serves, but by her knowledge and command of social resources. It is the exceptional home that does not require some means to supplement the service the nurse can give. Reputation is not built over night. Public confidence comes as the result of long and efficient service rendered. That miracles of healing do take place in the most inconceivable surroundings serves to preserve to the nurse her courage, and to the visiting nursing group the vision which must guide their future work. The touchstone of it all is not in the ornamental figures of statistical reports of visits made and "cases" seen, but in remembering that each "case" is a suffering individual. So will preventable ignorance, sickness, and poverty be eliminated. "Before we can socialize the individual," said Miss Foley, "we must individualize society."

Mrs. J. M. Cudahy was re-elected president of the board of directors,

Tell It to the People

THE great bulk of medical work, public and private," said Richard Cabot, thirteen years ago, "is still done by men—high-minded men—who believe that it is impossible to deal frankly and openly with patients." It is probable that this was even then an overstatement of the case; yet there has certainly been a marked and a gratifying tendency during recent years for the medical profession to take the public more and more fully into its confidence. The promise for next month of the first issue of a new monthly journal, *Hygeia*, to be published by the American Medical Association, is the latest manifestation of the new spirit in medicine.

Hygeia is "to interpret medical science to the public; to inform the layman concerning the fundamental facts of physiology and pathology; to keep him in touch with the advance that scientific medicine is making in the prevention and alleviation of disease." The demand for popular journals in this field has already been demonstrated, but it is profoundly significant that the medical profession of the country should go to the length of establishing a special journal for the enlightenment of the public. It is perhaps even more interesting that the primary emphasis of

the new periodical, as evidenced by its name, should be on prevention. *Hygeia*, it will be recalled, was the daughter of Aesculapius. Therapeutics attained maturity first, but the future belongs to prophylaxis. In so far as the individual physician and the profession as a whole become teachers of hygiene, will their greatest possibilities be realized.

Problems of Sanatorium Treatment

IT HAS been generally admitted by the leading members of the medical profession, and in particular by the tuberculosis experts themselves, that sanatorium treatment falls far short of the results hoped for twenty years ago. It had been thought that six months treatment would completely cure nearly all patients who were received in the incipient stage. The few sanatoriums that have followed up their discharged cases find that after five, ten, or fifteen years from 25 to 75 per cent of the patients are well and of those that have died practically all have died of tuberculosis. Many sanatorium physicians now urge a much longer period for a complete cure. Social workers, dispensary physicians, and private physicians in our larger cities complain of the fact that many patients return from sanatoriums apparently fit

for work, but relapse within a few months after their return and then find great difficulty in securing readmission to the same sanatorium or admission to another sanatorium as the condition is considered too far advanced.

Are the sanatoriums performing their full duty in this situation? Is it feasible for them to train their patients to perform work, light at first, but gradually increasing in amount, so that the patient will not be discharged until he is in fit condition to carry on his occupation? We know that this ideal is difficult to attain and that many patients desire to return home as soon as they feel well enough to be up and about; but surely the boards of managers and trustees of sanatoriums should take all possible steps to increase the length of stay for those patients who show a prospect of complete return to health and working capacity.

Many persons are recommending farm colonies and work shops for after-care. The question is raised as to whether or not it is feasible to perform this after-care and preparation for future work at the sanatorium. The Director of the Veterans' Bureau has announced that he is organizing some so-called "Convalescent Centers," to which men will be sent for prolonged convalescence and vocational training after the disease has been arrested by sanatorium treatment. The consultants on hospitalization to the Secretary of the Treasury have also provided generous space for pre-vocational training in the several sanatoriums which are being built by the government upon the consultants' recommendations.

The two greatest gaps in our present machinery for the care and prevention of tuberculosis are, (1) the detection of the early case and immediate provision for its treatment, and (2) the care of the patient discharged from the sanatorium, supposedly arrested or apparently cured. It is hoped that sanatorium authorities will carefully consider what future steps can be taken to provide at the sanatoriums the "work cure" which should follow the "rest cure."

The Wider Program of Anti-Tuberculosis Work

IN THE beginning of our anti-tuberculosis campaigns in the larger centers of population, emphasis was placed upon facilities for laboratory diagnosis; anti-spitting laws; the care of early cases in sanatoriums and the isolation and care of advanced cases. These measures have been continued with apparent success. The next steps were the organization of case finding machinery by the creation of tuberculosis classes in general clinics, the establishment of tuberculosis dis-

pensaries, and the employment of public health nurses. As time went on, general popular education by means of the tract, newspaper, lantern slides, and, more latterly, the film, has had the greatest value in awakening a widespread interest in combating this disease.

The leaders of medical thought have looked further into the problem and have seen that prevention should begin before adult life and endeavors should have been made by various methods to ascertain by means of physical examination the minor physical defects which exist among children of school age and to provide facilities for the removal of these defects. After, and in many cases before, this machinery had been organized, endeavors were made to give popular education on health, to instill in the minds of children the importance of healthful habits, and to furnish them with a means of acquiring these healthful habits.

It has not as yet been generally realized that a tuberculosis program cannot be complete without a well rounded out comprehensive public health program, which would include as a primary duty the creation and maintenance of a first class state and local health administration. To appreciate what the tuberculosis problem is, one must have an accurate knowledge of vital statistics with records of mortality and morbidity from various diseases; and in many states and localities this information is still lacking. To prevent tuberculosis one must prevent other forms of communicable diseases. Children must be well nourished, they must receive their regular allowance of fresh air, pure food and pure water, and these can be obtained only by means of the constant supervision of the health department. Further, the social and economic conditions of our modern life play an extremely important part in the tuberculosis program. Adequate housing facilities are essential and these should be sanitary and decent and such as not to permit of overcrowding. This can only be obtained by means of housing laws and supervision. Hours of work must be regulated; work in factory and shop must be controlled; proper safety appliances must be utilized to prevent the inhalation of noxious gases and harmful dusts. At the present time it should be a primary objective in the minds of all health workers, who are endeavoring to combat tuberculosis and other diseases, to secure the creation and maintenance of a satisfactory health department, both state and local, and a health department be cognizant of the fundamental principles of anti-tuberculosis work.

These fundamental principles can be summarized briefly under several headings. There

should be adequate case finding machinery which should include an enlightened public opinion as to the need of early and competent medical examination. This necessarily emphasizes the importance of having thoroughly trained and competent medical practitioners. For those who cannot afford the well trained private diagnostician, recourse must be had to the public dispensary. Visiting nurses, public health nurses and social welfare agencies will also materially assist in detecting early cases of tuberculosis. Public health laboratories are essential for diagnosis. When the case has been detected, facilities must be available for treatment in sanatoriums and other special institutions. Facilities must also be provided for the advanced case and also in occasional instances authority must be granted to health departments to enforce isolation for the careless consumptive. Finally, official and voluntary agencies must do all in their power to maintain a high standard of work in all the intricate branches of health work. With the constant development of the industrial and agricultural resources of the country, a higher standard of living may be obtained so that it may be possible for each individual family to earn a sufficient sum of money to live on such a plane that the danger of tuberculosis will be reduced to a minimum.

The Need of More Milk for Our Cities

EVER since the newer knowledge of nutrition made clear the preeminent importance of milk in our food supply, those physicians and health officers who appreciate the influence of nutrition upon the ability to resist disease have felt that more attention should be given to the problem of providing our urban population with a milk supply not only of satisfactory quality, but also of adequate amount. This feeling is intensified as we look over the statistics of city milk supply recently collected by the Committee on Municipal Health Department Practice of the American Public Health Association.

The advice of experts in nutrition as to the per capita consumption of milk needed to give the best results ranges from one pint to one quart per day. Not a single city reports a milk supply equal to the higher of these estimates, and even the lowest standard is apparently reached by only one city in ten. The average for the sixty-six cities reporting is 0.34 quart per capita per day and all of the five largest cities show per capita milk supplies very close to this average. Some might argue that this experience shows one-third of a quart of milk per capita per day to be an adequate community supply; but this view would

only be justified if it were true that all the people of these cities were well nourished or if we accept as "adequate" a condition which is far from being satisfactory. As was shown in our issue of last September¹ a food supply may be adequate not only for healthy maintenance but for growth and reproduction, generation after generation, and yet an increase in the proportion of milk in such a food supply will strikingly improve the health and vigor of the families subsisting upon it. It must also be remembered that the total milk supply of a city is not evenly distributed to all its families according to their needs, hence the supply should be large enough to provide a safe margin in this respect. According to a widely accepted dietary rule *every* family food supply should furnish a quart of milk per day for every child up to six years of age, at least a pint for every child from six to sixteen, and at least a half-pint for every adult. This is a *minimum* standard. Recent work shows² that optimum storage of calcium in the body of the growing child, and presumably therefore optimum development of bones and teeth, requires that the allowance of a quart of milk per day be maintained up to at least the age of twelve to fourteen years.

When we view the data of our city milk supplies in the light of this newer knowledge of what a really satisfactory per capita consumption of milk would be, it is plain that Clark and Collins of the United States Public Health Service are very conservative when they say that "probably the most important nutrition problem is to secure an abundant and safe milk supply at reasonable cost." We believe that, broadly speaking, American city milk supplies are now reasonably safe but are far from being reasonably abundant. The country is abundantly able to supply as much milk as is demanded; but the cities do not consume anywhere near as much as would yield the best returns in health and vigor. Naturally, the condition is worse in the southern than in the northern cities. For example, Boston shows a per capita consumption of 0.51 quart, Minneapolis 0.42, Denver 0.47, Pittsburgh 0.60, against Birmingham 0.13, Atlanta 0.14, Richmond 0.17, Memphis 0.15. Jacksonville, the home of a man who for some years has been a member of the National Commission on Milk Standards and a woman who has been one of the most efficient workers in the popular teaching of nutrition, makes a much better showing than other southern cities. The difficulties of materially increas-

2. Sherman, H. C., and Hawley, E., *Journal of Biological Chemistry* lili, 375, August, 1922, and *Journal of Home Economics*, xiv, 413, September, 1922.

ing the consumption and supply of milk in our cities are not insuperable, even in the South. The fluid milk industry is capable of considerable expansion to meet a growing market; and in addition to this there is the great potential resource of milk produced wherever economy indicates and preserved by any of the modern methods of drying or canning for use whenever or wherever needed.

The experience of the United States Public Health Service in the use of dried milk for infant feeding, recently published in full by Clark and Collins,³ has been gratifying in the highest degree. It was already well known through other publications of the Public Health Service that the war city of Nitro, W. Va., derived its milk supply entirely from dry milk and with very satisfactory results. The National Commission on Milk Standards has taken favorable note of the dry milk industry and has urged upon health officers a liberal attitude toward this new product such as shall encourage and not hamper its increased production and use. The Committee on Nutritional Problems of the American Public Health Association has done likewise, and has emphasized its belief that the production of dry milk is destined to play an important part in the food supply of the South where shortage of natural ice makes the handling of fluid milk especially troublesome and expensive. The manifest advantages of dry milk apply in greater or less degree to canned milk also, and as yet canning appears still to be somewhat the more economical process. Such at any rate is the most probable explanation of the fact that condensed and evaporated milks are still far larger factors in the milk supply than dried milk has yet become, notwithstanding the cordial reception accorded to dried milk and the fact that canned milk has always had to contend against a greater or less degree of prejudice. Any prejudice which tends to retard the use of either dried or canned milk is unfortunate and is opposed to the interests of the public health. A good grade of either canned or dried milk is good milk in concentrated form, and condensed milk like milk powder may be used interchangeably with fluid milk⁴ whenever circumstances make this desirable. Consideration of vitamin C need not enter to complicate this question if we accept the judgment of the Committee on Nutritional Problems of the American Public Health Association⁵ that *all* artificially fed infants should be given a small

amount of some such highly efficient antiscorbutic as the juice of orange or of canned tomato.

To return to our text, we earnestly recommend that the Committee on Municipal Health Department Practice repeat its inquiry as to the per capita consumption of milk in American cities at annual, biennial, or triennial intervals until a very material improvement shall have been effected. It may perhaps be found that the present situation is not quite so bad as it appears. Some cities may have failed to report the milk which they receive in canned or dried form and some health officers may not yet know accurately even the amount of fluid milk which their cities consume. But no health officer can any longer afford to remain ignorant on a point so important to the public health, nor to rest on his efforts to insure a safe milk supply so long as there is even greater need that he cooperate with the Red Cross and home economics workers in their efforts to educate the public to the importance of milk as food, and to a realization of the fact that the best interests of the public health call for the consumption of about twice as much milk, in some form, as our cities are now using according to the latest reports from their health departments.

Height, Weight and Malnutrition— The Complexity of the Problem

THE past year has been an active one in the study of malnutrition and its detection by the determination of height-weight-ratios. There is a growing recognition of the complexity of the problem and of the importance of fixing norms for particular groups of children before drawing deductions as to undernourishment from a given series of weighings. The report of a Committee on Statistics of the New York Nutrition Council¹ contains particularly valuable hints as to the disturbing influences of race and season, and the distinction between retardation and malnutrition.

The gradual perfection of our standards must be brought about by the actual determination of height-weight-ratios in groups of children of various types. For example, Clark, Sydenstricker, and Collins² have presented us with measurements of 14,335 native white school children in four southern states, which indicate results corresponding rather closely with the norms obtained by Baldwin³ from successive observations made year by year on 250 children in New York City.

3. Physical Growth of Children from Birth to Maturity. University of Iowa Studies in Child Welfare, 1921.

although the weight-height index obtained by the Public Health Service for girls rises in later years above that found by Baldwin.

In view of the general interest in Pirquet's pelidisi system⁴ the study conducted on 1,814 children in New York by Baker and Blumenthal⁵ is particularly significant. A 10 per cent deviation from the Wood scale of height-weight corresponded in this case rather closely to the results of clinical examination (22 per cent as compared with 25 per cent of the children undernourished) but the Pirquet pelidisi standard gave a much higher figure (33 per cent).

For the pre-school child we have, of course, the admirably exhaustive studies of Woodbury⁶; and for children over school age, the report of Frankel and Dublin⁷.

Imperfections there must always be in any plan of relating height and weight to malnutrition. These imperfections will surely decrease, however, as our knowledge grows. Meanwhile, "The scale in every school" has proved its value. In the words of Dr. Holt⁸, the most influential proponent of this movement, "the purpose of weighing and measuring children is not to collect statistics, but to interest the children themselves in health, and this it is bound to do."

The Veterinarian and the Public Health

THE debt which sanitary science owes to veterinary medicine and the advantages which will accrue to the public health through closer affiliation between those who are interested in the preservation of the health of man and those who labor with animals, are too little recognized. Not only is the trained veterinarian assisting in the solution of many problems of human pathology through research into the diseases of animals, but he may also be of incalculable value in preventing the spread of the communicable diseases of animals to man. By collaboration and an interchange of thought, the medical and the veterinary professions will receive much mutual benefit, while for the health worker, the veterinarian will prove an ally of the greatest worth. As a matter of fact, the eradication of several diseases common to man and animals, rests in the final analysis with the veterinary scientist.

Glanders, through the discovery and application of mallein, has become extinct in Great Britain; human rabies will disappear if the veterinarian will control his canine patients, while he may render great aid in the eradication of anthrax, foot and mouth disease, and cowpox. It has been stated that each year more than ten thousand British children die from drinking the milk of tuberculous cattle, of which it is estimated there are a million in England and Wales. The control of mange, ring-worms, actinomycosis, echinococcosis, trichinosis, the beef and pork tape-worms also fall within the purview of both animal and human public health, since they are inter-transmissible and there is also a broad common ground in the prophylaxis of the virus diseases in which there would be the fullest cooperation between veterinarians and sanitarians.

The time has come when the health worker who does not avail himself to the fullest extent of the assistance of his veterinary colleague is neglecting an opportunity of great potentialities, not only because of the intercommunicability of many animal and human diseases but also because by the study of the analogies between the pathological processes of man and those of the lower orders much knowledge may be gained which can be employed in the protection of the human species.

Public health is not a science standing in isolated grandeur. Rather is it a cooperating and coordinating focus at which meet all of those sciences which may assist in surrounding man with every safeguard which will protect and prolong his life.

THE function of public health nursing and the place of the nursing department in the municipal health organization are ably discussed on another page of this issue of THE NATION'S HEALTH by Dr. Charles J. Hastings, medical officer of health, Toronto. No division which forms an essential part of public health service presents greater possibilities or greater complexities than that of nursing. What municipal responsibility attaches to school health supervision; what bedside nursing shall be undertaken; what use in giving direction to general activities can be made of the first hand contacts of the nurse; what team play can be effected between the city nurse and other community resources; what means of constant intercommunication will assure unity of organization: all of these problems have been met in the flexible and efficient system evolved in Toronto. We commend it to the consideration of health officers and nursing organizations everywhere.

HEALTH IN INDUSTRY

*Problems Concerning Factory Sanitation,
Industrial Medicine, and the Health and
Efficiency of the Industrial Worker*

Cost Measurements of Industrial Accident*

BY JOHN L. TRAIN, SECRETARY AND GENERAL MANAGER, UTICA MUTUAL LIFE INSURANCE COMPANY, UTICA, N. Y.

IT HAS been well stated in the report on "Waste in Industry," published in 1921 by the Federated American Engineering Societies that three aspects are to be considered in estimating the economic loss or cost of industrial accidents: (1) The loss of productive labor on the part of workmen who are killed or injured, together with the cost of medical and surgical attention and the overhead cost in connection with the payment of claims. (2) The indirect loss to production due to the stoppage or slowing up of work when an accident occurs. (3) The injurious effect of frequent accidents on the morale of workers.

As a result of the various investigations and studies of statisticians and actuaries, it is possible to ascertain within a reasonable degree of accuracy and fairness, the loss of productive labor caused by accidents.

Taking the United States as a whole, there are approximately three million accidents per year, causing at least one day's disability. This figure will vary somewhat, depending upon decreased or increased industrial activity, but in a normal year with normal industry, this figure, based on the results of investigations in states which keep a complete record of industrial accidents, is approximately correct.

In 1917 a committee on statistics and compensation insurance cost appointed by the International Association of Industrial Accident Boards and Commissions, which committee consisted of many of the leading stat-

isticians and actuaries in the United States, made a report after a thorough investigation to the effect that the time lost was the most significant, stable and convenient expression of the economic cost of industrial accidents and stated that obviously it is only the loss of time due to accidents that is susceptible of satisfactory measurement. It is certainly true that the physical or physiological results cannot be reduced to tangible terms, and the cost in terms of human suffering can neither be estimated or expressed in cold figures.

The report of this committee further states that the economic cost of accidents cannot be measured in terms of the compensation paid, for no two of the American Acts agree as to the scale of benefits to be paid for specific injuries. The compensation cost of industries of equal hazard fluctuates enormously from state to state, and the greatest difference between the compensation paid and the economic loss is found in the relative importance of permanent disabilities.

The Index of Hazard

Further, wage loss, even if it could be accurately obtained, is not a satisfactory index of occupational hazard. Wages vary from occupation to occupation and from time to time, so that no constant relation can be predicated between extent of disability on the one hand and wage loss upon the other. The computation of wage loss, moreover, presents numerous difficulties, more especially in fatal and permanent injuries. It is not a correct assumption to state that the particular wage rates prevailing at the time of

injury will continue throughout the working life of the injured and it is still more difficult to compute the earnings of an apprentice or a minor who is just learning a trade.

The committee therefore adopted a table as a scale of time loss for weighing industrial accidents, applying a certain definite number of days lost to each class of disability. For example, for death and permanent total disability the economic loss was measured by six thousand days and for the injuries of a lesser degree a proportionate time expressed in days lost.

In 1919 an American Accident Table was prepared for the purpose of calculating the value of amendments to the various state workmen's compensation laws so that such calculation should be based upon the last available accident distribution. This table of 100,000 cases shows the distribution of accidents by classes of injuries. That is, out of 100,000 accidents there were 762 fatal cases, 62 permanent total, 3,788 permanent partial and 95,388 temporary total cases. The duration of the temporary total disability cases was again divided as to the actual length of disability.

We, therefore, have available a scientific method of computing economic loss, inasmuch as we know approximately the number of accidents occurring in the United States per year, the classification of such accidents by kind and duration of injury and the cost of such injuries expressed in the number of days lost.

We find, therefore, by this computation and with an average daily wage of four dollars, taking the current figures of the New York State Department of Labor as a fair average,

*Read before the Sixth Annual Industrial Conference of the State of New York, Buffalo, November 23, 1922.

that the economic loss of productive labor per year approaches the vast sum of \$1,010,500,000.

Taking the state of New York by itself, we find that for the year ending June 30, 1921, there were 294,469 accidents. Computing the cost of these accidents on the basis of the American Accident Table and the table adopted by the International Association of Industrial Accident Boards and Commissions for time loss, the total number of days lost would amount to 28,925,592 at a cost of four dollars per working day or \$99,172,000.

It is interesting in this connection to ascertain what proportion of this economic loss is made up by the benefits provided under the New York State Workmen's Compensation Law considering the amount directly received by the injured employee and his dependents and paid physicians and hospitals for medical treatment.

Loss Approximated

Our investigation discloses that the total amount of incurred workmen's compensation losses for the year ending June 30, 1921 of all insurance carriers and self insurers amounted to \$24,136,000 and the medical cost, including hospital \$5,007,000, or a total of \$29,143,000. This, of course, does not include any overhead cost of disbursing the benefits or for any investigation or adjustment of the claims made under the law and, further, it does not consider any outside benefits which the worker or his dependents may receive as a result of personal accident insurance. It would therefore seem that the employee receives direct benefits under the New York Workmen's Compensation Law of approximately 30 per cent of the economic loss. The proportion in New York is greater than in any other state in the United States due to the more liberal provisions of the Act. A fair average of the compensation benefits to the economic loss in the other states in the United States, having workmen's compensation laws, would amount to approximately 20 per cent.

Of course, as far as New York state is concerned it is possible that the application of the American Accident Table to divide the number of accidents by classes of disability is not strictly accurate, but the State Industrial Commission has not yet issued any figures with a complete tabulation of the injuries by classes of disability. It is, therefore, quite possible that the classification of injuries in New York, owing to the gen-

eral average non-hazardous class of business, that is including no coal mining and very little other mining, explosive manufacturing, etc., that the actual economic loss is less than shown by the foregoing computation. It is certainly not more.

It is, of course, impossible to measure by any statistical figures the indirect loss to production due to the stoppage or slowing up of work when an accident occurs but it is known by every employer that such an accident effects production in his plant very seriously. The employee loses confidence in his own safety, his nerves are affected and, while he may thus be rendered more cautious, he carries the point to such an extreme that for some time after the accident, there is a slowing down of his own productive capacity.

It is equally impossible to measure in any concrete terms of cost the pain and suffering to the injured employee and the readjustment of the lives of those dependent upon him.

The country as a whole—industry particularly—is confronted with an annual economic loss due to accidents aggregating \$1,010,500,000. That is a fair estimate, possibly more rather than less is involved, due to additional costs which have not been considered such as stoppage or loss in production, and the training of new workers to replace injured workers.

Humanitarian Cost Great

The economic loss in the state of New York alone may fairly be considered to amount to approximately one hundred million dollars, a loss that is subject to scientific measurement and probably has not been appreciated before by employers or business men. The employee or his dependents are paid but a comparatively small proportion of the actual loss to them and they have a right therefore to ask that the injuries and disabilities causing their economic loss be decreased to the greatest extent possible. This is not to say that the economic loss is caused directly by the employer or that the employees are not in part to blame, but whatever the manner of dividing and apportioning this loss between employer and employee, it actually exists as a waste in industry in the loss of man power and human resources which, above all things, should be conserved.

While we have for the purpose of this paper tried to measure the economic cost of accidents in the terms of figures, the humanitarian side, that is physical pain, the mental

anguish, the suffering and distress both to the injured employee, his family or dependents are of much greater importance and the cost of accidents from this viewpoint alone is so enormous that no employer can offer greater service to his fellow-men than to do everything within his power to eliminate the cause.

Sanitary Safeguards in Travel In U. S. and England

Much is heard from time to time in public health circles in regard to certain laxities and needed emphases in the health protection of the general public. Several accounts of the sanitary practices in this country imposed upon common carriers have been published in recent months in *Public Health Reports* and in *The Nation's Health*. Without in any way seeking to minimize the importance of increasing effort to standardize safe methods throughout the country, the following comment from the current issue of *The Lancet* (London) furnishes an interesting basis for an estimate of the progress made in the United States in this respect:

The amalgamation (recently accomplished) of an immense number of competing railroad managements into a few well distributed groups has given rise to new prospects of efficiency. For ourselves we entertain the hope that travel may not only be rendered hygienic, but may increasingly become an object lesson in the essentials of health to the traveling public. At the present time the sanitary conveniences of the large railway stations in London and the great cities, although they lack the charm of, say, Aberdeen or Basle, are nevertheless clean and efficient; but the water closets and urinals of most suburban and rural stations are unclean and inefficient—in many cases stronger terms would be appropriate—while the facilities for women are penurious. Waiting rooms, if not warmed, should at least be clean, and we may hope that a time will come when it will be possible for any adult traveler to wash his hands at a railway station and for any child to obtain a drink of clean water.

Much, of course, depends on the cooperation of the traveling public, but railways have already done a great deal to discourage the ugly habit of expectoration; traveling manners are improving and the companies should maintain their lead. Our Roumanian correspondent tells us that the sanitary board of the state railways is setting up certain standards regarding ventilation and cleanliness in consultation with members of the medical profession. Perhaps the Royal Sanitary Institute of Public Health could initiate some rivalry among the railway directors in these matters, for undoubtedly hygienic travel might be made a valuable object lesson.

How Industrial Accidents Are Being Prevented*

BY ARTHUR H. YOUNG, MANAGER, INDUSTRIAL RELATIONS, INTERNATIONAL HARVESTER COMPANY, CHICAGO, ILL.

THE Eleventh Annual Congress of the National Safety Council was held in Detroit early in September, 1922. Some two thousand delegates were registered, representing every state in the Union, every province of the Dominion, as well as many foreign countries. Each delegate not only participated in the formal discussion of broad and fundamental factors of accident prevention, but it is safe to say that each, in addition, had at least one wholly original "stunt" or personal experience to contribute to the general program or to private conversation. The report of this convention, when published in the proceedings, will constitute a volume of fifteen hundred pages. Even this vast volume enables only a partial answer to the topics assigned for this discussion.

This mention is made not gratuitously to advertise the National Safety Council, but merely to indicate the scope of the subject, and the impossibility of presenting in one article more than broad general outlines of the present scope and activities in industrial accident prevention.

As a broad, social movement, "safety first" is less than two decades old. All of us have seen its birth, its period of adolescence, and possibly some evidences of maturity, but only the rashest of persons would hazard a prophecy as to what safety shall encompass ten years hence.

In these first pioneer days, the answer to "How are industrial accidents being prevented?" would have involved a mere recital of mechanical safeguards: "Gear covers; countersunk set screws; safety couplings for shafts; hand-rails and toe boards for scaffolding; walks on crane runways, bridges and trolleys; goggles; guards on flywheels, belts, pulleys and shafting. These at first were the paving blocks on the royal road to an accidentless industrial system.

But work on such a basis had no more than started when it was held as inadequate to bear the traffic of a necessary and comprehensive program as would be the roadways of a decade ago to carry the motor truck fleets of today.

There came the quick realization that safety was not primarily a problem of physical equipment, but rather

Safety first tends to supplement haphazard procedure by thought-out reactions. Its logical development is that engineering standards have grown out of well considered accident prevention.

It was inevitable also that any serious attempt to understand the "personal equation" in accident causation would lead to the recognition of types of workers and put a premium upon training and stability which in turn improves industrial relations.

On the physiological side the equivalents of energy required on a given job are becoming known and the hygienic or psychic influences affecting the worker adversely are being controlled by progressive management.

one of education; that, while it could be held necessary and important for equipment to be fool-proof, there could be no prospect of success until every employee, and indeed every member of society, was converted from "a naturally careless to habitually careful person."

And then began the campaign of education—by safety committee meetings; bulletin boards; prize contests; movies; home, school, and public meetings which has developed, through an evolution that in many instances reads like a romance, into (but not culminated in) our present day program, a meager outline of which would include—

Guarding Physical Equipment

"As it was in the beginning is now and ever shall be." This mental attitude represents the starting point of industrial safety. The initial manufacture of standardize codes and the including of all safeguards as an integral part of the machine by its builders were relatively easy to achieve. As one indication of the refinement to which this factor has progressed the electric overhead traveling cranes is of interest. A few years ago it consisted barely of a trolley carried by two steel bridge girders, and mounted on runways that provided no real clearance between

the ends of the bridge and the building columns. Somewhere there was suspended or affixed an operator's cage and the assembly constituted one of the most deadly agencies of modern industry. The operator "shinned up" a lattice column, crawled to his perilous cage, guessed at signals as his knowledge of the idiosyncrasies of signallers best permitted, and moved his load (sometimes safely) through and over groups of workmen dimly discernible beneath him. Dismembered, crushed, and dead bodies of painters, riggers, and repair men marked the passage of the crane on its runway. Repairs or adjustments to the bridge equipment were accomplished on swinging scaffolds and furnished evidence of the descent of man from the ape by the manner in which the repair men clung to the bridge while working over the heads of their fellows below.

The crane of today is purchased from designs and specifications prepared by the safety engineer, has bridge walks with hand rails and toe board across its full length, the trolley is floored and railed, the runway is bracketed out from the building columns to provide not only for man clearance but a floored and railed walkway. The commodious cage has all of its equipment safely housed and insulated. Its design and suspended lights must provide clear view of the floor below. Access to the cage and to the bridge walks from the cage is by means of railed stairways; locked safety switches insure the safety of repair men against careless starting of the machine. Standard signals definitely indicate its movements, warning gongs and crane hooks clear the path before the load; fenders guard the bridge truck wheels, while specially posted guards protect transient workmen on the runways. The trolley wires and all other charged parts are protected from accidental contact. Limit switches make it impossible to "run the blocks." Cables are regularly inspected. Sheaves and blocks are so designed that they or their load cannot drop in the event of breakage. Bumpers and dynamic brakes soften the shock of collision. Roof trusses no longer whisk repair men into eternity. As with emery wheels, goggles, power plants, switch boards, blast furnaces, and machine tools of every description—the physical equipment of the modern plant is becoming as

*Read before the Sixth Annual Industrial conference of the State of New York, Buffalo, November 23, 1922.

nearly fool-proof as human ingenuity and zeal can make them. Cost in most cases is a matter of secondary consideration.

Plant Organization

Safety first is increasingly becoming, as our astute engineers have directed, an integral part of the manufacturing curriculum, rather than a separate and distinct specialty, and we see today our corporate officers, major plant executives, engineers, draftsmen, foremen, and workmen intimately concerning themselves with the "Always Be Careful," the so aptly termed "A, B, C" of safety.

The recent congress of the National Safety Council was not unique in the representation of directors, presidents, officials, and workmen within single session programs. That is an established routine in the safety schools and instruction courses conducted in more than fifty cities in the United States and Canada.

No plant is well organized today that does not include as fundamentally important and necessary to efficient manufacturing, the enlistment of each and every individual concerned therewith actively into the everlasting campaign for the elimination of accidents.

Statistical Record

Federal, state and civic agencies; insurance, organized labor, and engineering societies; community safety councils and industrial safety engineers have so standardized their methods of recording data that we have today a complete historical record of accomplishments in accident prevention work. More important still, we can analyze accurately both physical and mental hazards for the intelligent direction of our efforts. It may safely be said that the forces of "King Carelessness" are completely unmasked—their strength, their direction of attack, mobility, reinforcement possibilities and means of sustenance are fully known through the wealth of statistical data which are at the command of any interested person. Hours could be spent in recital of the good work of the United States Bureau of Labor Statistics, the life and casualty insurance bureaus, the National Safety Council, and committees of safety workers in securing dependable primary data and laborious analyses thereof. Such work is not spectacular and seldom is fair acknowledgment made to those who serve in such capacity of the fundamental value of their work.

A comprehensive program for safe-

ty education within the shop includes: (1) Physical examination of applicants for employment. (2) Periodic re-examination of employees. (3) Proper introduction of the new employee to his job, his foreman, and fellow workers. (4) Safety committees. (5) Schools of instruction for safety committeemen. (6) Bulletin posting. (7) Interdepartment and interplant safety contests. (8) Prizes for "no accident" periods. (9) The "new broom" "crowing rooster" "bulls-eye" and similar contest trophies. (10) Rule books for employees and foremen. (11) Drawings and specifications for standard equipment. (12) Lectures and movies. (13) Suggestion system. (14) Plant publication. (15) Foremen's training courses. (16) Special drive days, such as "good ladder day," "chain and cable inspection day," "good house-keeping week," etc. (17) Pay envelope inserts of slogans and sermonettes. (18) Safe clothing. (19) Safe practice inspections. (20) Safety museums and "bad tool morgues." (21) Fitting and specially grinding goggles. (22) Fire prevention. (23) Sanitation. (24) Ventilation. (25) Warning signs and lights. (26) English classes. (27) Fatigue studies.

This score or more of activities have been listed without regard to logical sequence or relative importance, but they serve to indicate the versatility and ingenuity of the safety inspector of today. The list may readily be lengthened to hundreds of topics by "listening in" on the conversation of the many serious minded men and women who attend this and similar conventions.

Outside Educational Program

Our public safety work of today is but the logical development of the industrial safety movement, which recognizes the necessity, if success is to be attained, not only of inculcating habits of caution in youthful minds during the school years, but of so creating and maintaining an atmosphere of safety in the homes, school, on the street while driving or walking, and practically during all of our waking hours, as will cause each of us automatically and perpetually to substitute "think" for "forgot," "caution" for "recklessness," "protection" for "destruction," and thereby substitute life and happiness for death and injury.

This is not a full story of public safety work; my point is simply that our present day activity is the result of and receives its support from the industrial accident prevention movement.

In conclusion I wish to emphasize the great moral stimulus to intense and continued effort which develops from the very nature of safety work. Experience everywhere brings out the heartening and wholesome moral influence derived from association with men, women and children engaged in the conservation of human life and the elimination of painful injuries, and the stopping of misery of body and spirit that so frequently follows in the wake of preventable accidents. That moral stimulus is definitely a factor in the daily lives of American workmen, managers, and owners of industry.

Pre-cooling of Mine Air to be Studied

The deepest mine in the world, man's farthest approach toward the hot center of the earth, is the objective of Dr. Thomas T. Read, Chief of the Information Service of the Bureau of Mines, who represented the Interior Department at the Brazil Centennial Exposition at Rio de Janeiro. About 150 miles west of Rio the St. John del Ray Mining Company has burrowed in the earth, following a rich vein of gold ore, until the workings are nearly a mile and a quarter beneath the earth's surface. The temperature rises one degree for every 120 feet in depth and on the lowest level (6,426 feet) the temperature of the surrounding rocks is 118°F. No one could work at such a temperature, of course, and it is only through providing abundant fresh air forced in by fans, that the men can work effectively in the St. John del Ray. This mining company has tried the experiment of refrigerating its fresh air before forcing it into the mine, and the purpose of Dr. Read's visit is to ascertain whether precooling the air is enough of a success to justify its adoption in those mines in the United States where high temperatures are encountered in the deep workings. Questions in atmospheric control involved have very wide applications.

St. Paul Sliding Salaries

The City of St. Paul is now definitely committed to a plan of fixing the salaries of its municipal employees on a basis which makes the compensation automatically adjustable to the rise and fall in the cost of living. By this plan seventeen grades of service are established, excluding certain skilled and common labor employments.

Adequate Records of Lost Time in Industry

Prevention Waits Upon Full Reports and Careful Analysis of Industrial Morbidity

By L. R. THOMPSON, SURGEON, AND D. K. BRUNDAGE, ASSISTANT STATISTICIAN, U. S. P. H. S., WASHINGTON, D. C.

WE HAVE been so long studying the causes of death that we have almost lost sight of the fact that there is any such thing as sickness, and, reliable as death records have become in the last few years, they are almost useless from an occupational standpoint.

The standard certificate gives one question to occupation, and that question deals only with the general trade to which the deceased belonged. It does not attempt to classify him as to his employment in the trade, nor does it attempt to elicit the period of time he was engaged in the trade. On the other hand, our knowledge of health hazards in industry, for instance, that coal dust is innocuous and that silica dust is dangerous as referring to tuberculosis, is a result of careful review of mortality statistics, which show that the coal miner has a lower death rate from tuberculosis, and that the worker in silica has a higher death rate from tuberculosis than the average man.

The mere fact that we spend at least one-third of our time in our trade cannot but have a definite bearing on our lives. Collis and Greenwood¹, in studying the relationship of tuberculosis to certain environmental factors, found that factory employment had a direct bearing on the prevalence of tuberculosis in the early years of life, it being even a more important factor than overcrowding in these years. If factory employment, in an industry where there are no definite health hazards, is a factor to be given consideration, how much more important from a health standpoint are those industries where our mortality statistics, vague as they are, point to definite health hazards?

For a considerable period of time, the Public Health Service has been carrying on a campaign urging the keeping of adequate sickness records in private industries. The reasons for this campaign are stated in the following five points:

(1) It is believed from a standpoint of business efficiency that ab-

senteism and its causes, relating as they do to production, have need of close study.

(2) Our present-day knowledge of the dangerousness of individual health hazards is based on mortality statistics. We have but an indefinite idea of either the diseases caused by these hazards or the resulting time lost through disability.

(3) The basis of reasonable standards for the protection of the health of the industrial worker can only be obtained where reliable sickness records indicate the effectiveness of the protective measures.

(4) The efficiency of the factory in minimizing its known health hazards, can only be judged by comparing its sickness records with other plants engaged in the same class of work.

(5) Standardizing the sickness records used by private concerns makes possible accurate comparison, where before, even though the data were most valuable, it was collected in so many different ways as to make comparison impossible.

Public Health Service Aids

To a limited extent, the Public Health Service has, as a manner of encouraging the keeping of adequate sickness records, agreed to assist in tabulating the data collected and analyzing the results. As part of these data there have been received monthly reports from sick-benefit associations having a waiting period of one week. We have recently tabulated the reported cases of certain of the larger sick-benefit associations in comparison with the average frequency of sickness of all associations reporting, for the year 1921. The results are very interesting. We found that the average frequency of cases of sickness and non-industrial accidents causing disability for eight consecutive days or longer among 75,000 industrial employees in 1921, was 98 cases per 1,000 persons. The lowest rate was 48 cases per 1,000 persons, and the highest rate was 349 cases per 1,000 persons, making the range variation of more than 700 per cent. If sickness frequency can vary between 48 and 349 cases per 1,000 per-

sons, an almost unlimited opportunity is afforded for reducing disability occurrence among the employee groups whose sickness experience is considerably above the minimum rate of 48 per 1,000.

Among the companies which had rather high sickness rates, was a public utility company. The rate for this company was 143 cases per 1,000 persons. In order to ascertain if the men or women employees were causing this high rate, we tabulated the cases separately by sex. Ordinarily, sex is a considerable factor in the sickness frequency rate. One can expect a female sickness frequency rate 50 per cent greater than the male rate, at least as regards serious morbidity (i. e., cases lasting eight days or longer). But in the public utility company mentioned, sex did not explain the rate; the rate for the men employees of the company was 46 per cent above the average rate for males, and the rate for the women employees was 70 per cent above the average sickness frequency rate for females. Nor were these percentages due to small numbers, for there were 2,600 men in the association, and 440 women members.

The classification by sickness causes was interesting. The rates for several of the diseases and disease groups were about average among either sex. Cases of rheumatism and lumbago were 50 per cent below the average among the men and about 35 per cent below the average among women employed by the company. Among the men there was an excessive number of non-industrial accidents. But the diseases that really caused the high rate in this group were the respiratory troubles, which occurred 110 per cent oftener among the men and 142 per cent oftener among the women than one would expect if the average rates are taken as criteria. There was no tendency for one respiratory disease to monopolize the situation; all the respiratory illnesses except pneumonia were present oftener than the average frequency. The sickness rates have therefore given us a sort of definition of the problem of sickness in this company; they constitute a challenge and

1. Collis and Greenwood: *The Health of the Industrial Worker*, P. Blakiston's Son & Co., New York, 1921, p. 136.

indicate the opportunity in disease prevention work in this association. Another company may have a different problem, but the above may suffice as an illustration of the usefulness of a simple analysis of sickness data.

Comparisons Made Possible

A number of companies are now keeping track of every day lost from work by employees on account of sickness. A large company in Ohio found that its 1,300 office workers averaged 8.15 days lost from work on account of illness during the year ending January 31, 1921. Curiously enough, the annual rate for the employees of the U. S. Public Health Service, based on eight months experience ending in May of 1922 came out exactly the same figure. The commonly accepted estimate is 8 working days per person per year. Just as we were beginning to think that there probably was not very much variation in the sickness severity rate, the National Cash Register Company came out with the announcement that their 6,000 employees lose on the average only 1.5 days per person per year. Estimating every employee-hour saved from sickness as worth forty cents to the company, they claim a saving of \$120,000 annually because they had been able to reduce their disability rate so far below the average.

Now that it has been demonstrated that a rate of 1.5 days per year is possible of achievement, does it not seem about time that we began to compare notes in industrial morbidity work, and find out what the minimum rates are for different diseases and groups of diseases, and where our excess disability occurs?

What is the most practical method of getting together on this proposition? It would seem that the most feasible approach is through the medium of the monthly report. Practically all medical directors have some form of monthly report. And most industrial physicians are ready to admit that there is room for improvement in the character of the monthly report made. Instead of having the monthly report simply a count of the number of treatments, the number of redressings, the number of visits to patients, the number of physical examinations, etc., why could not the monthly report be made an instrument of actual helpfulness to the industrial physician? Is not there a need for comparative reports so that we can learn what diseases are causing an excessive amount of disability in a given plant, and can trace down

the excess disability to specific departments or groups of individuals? When attention is directed to the important facts disclosed from month to month in comparative reports, it is believed that we will accelerate the progress is disease prevention work. There is experience to substantiate this belief. A few years ago the Equitable Life Assurance Society inaugurated comparative monthly reports of accident frequency in the industrial establishments insured with them. According to their director of safety and personnel, the reports revealed so many weaknesses in the defense against accidents, and proved such a stimulus to preventive endeavor that reductions of 25, 50, and even 75 per cent in some instances could be attributed to the helpfulness of their comparative monthly reports.

Not all questions, of course, could be included in a brief, current analysis of industrial morbidity. The monthly reports should be supplemented with a more detailed, but still comparative, annual analysis. As an example of the sort of question that ought to be investigated in an annual analysis is the matter of influence of length of service upon the sickness rate. The B. F. Goodrich Company of Akron, O., Norton Company of Worcester, Mass., Hood Rubber Company of Boston, have found that the frequency of disability cases varies considerably according to length of service with the company.

Sickness and Turnover

Sickness rate frequency among employees of the Goodrich Company who had been with the company for five years or more was only one-fourth of the rate for the group which had been in the company service for less than three months. It has been suggested that in every plant there will be found a correlation between sickness and labor turnover. Why is the new employee sick two or three or four times as often as the old-timer? This is a point well worth inquiring into.

Referring again to the high rate of respiratory troubles in the public utilities company previously mentioned as varying from 110 per cent above the average among men, and from 142 per cent among women in one individual establishment, to one interested in industrial hygiene, naturally, the first inclination was to note the health hazards in this particular plant, and they are listed as follows: (1) Sudden variations in temperature; (2) dampness; (3) inorganic

dust; (4) acrolein; (5) amyl acetate; (6) benzene; (7) lead; (8) methyl alcohol; (9) sulphuric acid; and (10) turpentine.

Of these ten industrial hazards, all except lead are known to cause irritation to respiratory organs. It would seem therefore the reasons for the high respiratory rate are evident, and that this plant has in its sickness records indisputable evidence that measures used for the control of the above industrial hazards, if any such control is attempted, are both inefficient and inadequate.

The subject has been dealt with briefly, since our idea has only been to add another concrete example of the value of sickness records, and to bring out clearly their intimate relationship to the study of lost time in industry and to a large measure their dependency on preventable causes.

Movement for Federal Control of Child Labor

Those states which today permit the employment of children under fourteen years of age rank with Japan, China, and India in the protection which they give to working children, declares Miss Grace Abbott, chief of the Children's Bureau of the U. S. Department of Labor. In her annual report she points out that nearly all the civilized western nations afford their children the protection that a number of American States withhold—that of a fourteen-year age minimum. The extent, she says, "to which the children of the United States have suffered from the nullifying of the Federal child labor tax law"—on May 15 of the present year by Supreme Court decision—"may be measured by the fact that only thirteen states meet in all particulars the standards of the Federal law." Since a previous attempt by Congress to bring child labor under Federal control had also been declared unconstitutional, the Supreme Court "seems to have made the issue clear," the report says, "either we give up the plan of a Federal minimum and rely solely upon the states, or we undertake to secure a Federal amendment definitely giving to the United States Congress the power to pass a child labor law."

A constitutional amendment which would secure to the children "all the advantages of our Federal form of government by giving to Congress the right to establish a Federal minimum and leaving to the States the right to raise and not lower standards," is recommended by Miss Abbott.

The Status of Child Labor in Ohio*

Administration of School and Labor Laws Needs to Be Harmonized

By EDWARD N. CLOPPER, PH.D., SECRETARY, CINCINNATI CHILDREN'S BUREAU, CINCINNATI, OHIO

WHAT is child labor? What is a child? It is hard to answer these questions nowadays. Time was when a child was a very young person indeed, but modern methods of care and protection and modern social legislation have extended the period of childhood until now any one under the age of eighteen years is technically considered a child for social welfare purposes, just as in the field of law a person who has not attained to his majority has long been technically known as an infant. But popularly, a fifteen or sixteen-year old girl is not called a child, but a girl, perhaps a flapper, and similarly with a boy of such age. The usages of the technician are not often the usages of the people. However, for the purposes of this discussion, let us say that a child is a person under the age of sixteen years.

What then is child labor? One might say, off-hand, that it is any work that a child does, and this definition may be acceptable to the extremist, but there is such a wide range in the kind of work that children do, as well as in the conditions under which the work is done, that we must differentiate if we are to be reasonable. Raymond Fuller distinguishes between desirable and undesirable forms and conditions of work for children; the desirable he terms children's work, and the undesirable, child labor. This distinction is based upon the consideration that all children should do some kind of work, and that it should be educational, developmental, and recreative in character; this is children's work. On the other hand, work which is not of this character or which is carried on under conditions inimical to the growth and development of the child is anti-social, and therefore to be classed as child labor. In a word, children's work is educative, child labor is exploitative. This conception recognizes the disciplinary value of suitable work for the purposes of child training as well as its educational value, while on the other hand, it condemns all forms and conditions of employment which result in abuse of childhood. So we may

venture to define child labor as any employment of a person under the age of sixteen years, whether for wages or not, whether under the direction of others or not, which interferes with his growth, development, health, education, training, or proper measure of recreation.

Decrease Scrutinized

With this distinction in mind and accepting this definition, let us see what is the extent of child employment in the United States. Our only authoritative source of information for the country as a whole is the national census, and in consulting its figures we are gratified to find that in the decade from 1910 to 1920 there was an absolute decrease in the number of children 10 to 15 years of age inclusive, reported as gainfully employed, from almost two million to slightly more than one million. The reduction amounted to 46.7 per cent. This is a remarkable showing and it becomes all the more noteworthy when we consider that while the number of child workers was going down, the number of children was going up, for of course, the child population increased during this decade. As a matter of fact, the number of children from 10 to 15 years of age increased 15.5 per cent in this ten year period; hence the decrease in the number of child workers in proportion to the child population becomes very impressive. In 1910, the government tells us, 18.4 per cent of all children 10 to 15 years were employed, as against only 8.5 per cent in 1920.

Unfortunately, the figures are not so cheering as they appear to be. One naturally assumes that those for 1910 can safely be compared with those for 1920, but this is not the case. The census, of course, does not represent conditions as they exist throughout the year, but as they exist on a certain selected day. In other words, a census is a cross section revealing conditions as they are found at the time when the cross section is made. We find that the figures for 1910 represent conditions on April 15 of that year, while the figures for 1920 represent conditions on the first day of January of that year. Now, there is a

good deal of difference between conditions in the middle of April and on the first of January, and this is especially true in the field of labor because of the seasonal character of a good many occupations. Forms of work which are active in the middle of Spring may be dormant in the middle of winter, and therefore cross sections made in these seasons are not wholly comparable. In the matter of child employment, this element of error in the comparison of the figures for 1910 with the figures for 1920 is probably considerable because the chief occupation in which children engage is agriculture and, while agricultural work is fairly active in the middle of April, it is largely at a standstill the first of January. We expect to find a large number of children engaged in agricultural activities of one kind or another in the Spring, and as a matter of fact 72 per cent of all the child workers reported in 1910 were returned as in agriculture, and we also expect to find but few reported in such work in mid-winter; and yet the number reported in agriculture in 1920 is again far larger than in any other kind of work—61 per cent being returned as engaged in this field. The contrast between the two census is therefore not nearly so great as one would be justified in expecting, when the difference in the census dates is taken into consideration. After having allowed for the difference in conditions existing at the different times when these two cross sections were made, we still find a gratifying decrease in the extent of child employment. Of this there can be no question.

The decrease has taken place in spite of the increase in child population, and moreover we must remember that not all the children reported as in gainful occupations in either 1910 or in 1920 were undesirably employed, for many of them were doing children's work rather than child labor and profiting from their employment rather than suffering from it. The reporting of a child by the census as gainfully employed does not necessarily mean that he is not attending school, or that he is being in any way abused. It is often assumed by care-

*Address before Ohio Welfare Conference, Columbus, O., November 2, 1922.

less thinkers that the census figures on child employment represent a wholly undesirable situation in which all the children reported are being exploited in mines and factories and denied the advantages of education. As a matter of fact, the figures include every form of occupation, desirable and undesirable, and whether interfering with school attendance or not, but it is impossible to determine what portion of the total are child workers, and what portion are child laborers. All we can be sure of is that they are neither all child workers, nor all child laborers.

Schools Cause Decrease

What is the great numerical decrease and the still greater proportional decrease in child workers due to? For one thing, laws restricting the employment of children were very generally strengthened in the period between the census, while at the same time standards of enforcement were raised and greater provision made for administration; that is, both the means and the method of restriction were improved. At the same time there was development of schooling facilities and strengthening of school attendance laws and of machinery for their enforcement; courses of study were made more practical and more attractive, and in this way large numbers of children and their parents came to look upon schooling as preferable to employment during the years of childhood and adolescence. Sentiment grew against child labor and for children's work.

One factor in this change has, however, been removed since 1920, namely the Federal law concerning the employment of children in certain occupations. In 1910 there was no Federal law in this field and when the census was taken in 1920, one was in force, but since then it has been declared unconstitutional and undoubtedly some children who would not now be employed if it were still effective, are at work. It provided that factories, mines, and quarries had to pay a prohibitive tax if they employed children under fourteen years of age at any time, or children between fourteen and sixteen years of age at night or more than eight hours a day. Most of the children under sixteen years of age in this country live in states where these provisions are in force under state laws, and indeed a large number live in states whose standards are considerably higher, so that assuming that the enforcement of state laws is effective, the annulling of the Federal law has not thrown down the

bars to the employment of any great number of children.

But what of Ohio? When we look at the census figures for this state, we find that the absolute decrease has been even greater than in the country at large, namely 57.7 per cent, and the proportional decrease is also greater inasmuch as the child population of the ages under consideration increased 17.5 per cent. In 1910, 8.4 per cent of all children from ten to fifteen years of age were employed, as against only 3 per cent in 1920. So while the Nation has cause to congratulate itself upon the great reduction in child employment, the state of Ohio has all the more reason to do so. Unlike the United States as a whole, the field which most working children enter in Ohio, according to the figures, is manufacturing and mechanical industries. The field ranking next is trade, and agriculture comes third; but we have reason to believe that if the census had been taken in April instead of in January, the number in agriculture would have been greater. We know that agriculture is a leading occupation in Ohio and that it is much more active in the spring than in mid-winter. We know, moreover, that there are in this state highly specialized forms of agriculture in which large numbers of families are employed in the appropriate seasons; this is true in the cultivation of sugar-beets, onions, grapes, berries, and orchard fruits. In Hardin County the cultivation of onions is very extensive and labor is brought in from every direction. Children are used here in the spring, summer, and autumn and of late years their employment in this work has taken on aspects that are not unlike the conditions that obtained years ago in manufacturing, for the state labor laws do not apply to children in agriculture and such children are affected only by the school attendance law which provides for the issuance of work permits to those under eighteen years of age. The use of children in this way has become so extensive and so open to attack similar to that made upon the employment of children in factories and stores in the past that measures will have to be taken to afford the necessary protection. Specialization in agriculture is ushering in the same evils that attended specialization in industry, and they will have to be controlled in the same way.

If Ohio's laws, even as they are at present, were well enforced throughout the state, there could be but little child labor. Newspaper selling, domestic service, and agriculture are about

the only forms of work open to children under sixteen years of age, and these are open to them only outside of school hours. The problem in Ohio, aside from the agricultural situation, is largely a problem of administration. The child employment and school attendance laws are on a high plane and it has long been recognized that they must be complementary, yet, although they are twins, the administrative system of one differs radically from that of the other. It is strange that the state should be careful to harmonize the provisions of two laws so closely related as these and yet establish wholly different systems of administration for them. The labor law is administered by state officers with no local assistance, while the school attendance law is administered by local officers with no state supervision. We need a combination of state and local service in the administration of both of these laws just as we have a combination of their provisions. The state and the local community must join hands and each realize its responsibility and discharge its obligation cooperatively with the other if the situation is to be satisfactorily handled.

Metal-Mine Dust Study by Bureau of Mines

For several years the Bureau of Mines has studied dust and ventilation in metal mines as affecting the health, safety, and efficiency of underground workers. A cooperative agreement was made in 1915 with the U. S. Public Health Service; since that time field observations in metal mines in Arizona, California, Idaho, Montana, Michigan and Nevada, and less extensive observations in several other states have been made by mining engineers of the U. S. Bureau of Mines, and doctors of the U. S. Public Health Service. The work, in general has been conducted along the lines followed by South African investigators in the mines of the Rand in connection with study of miners' consumption, but a much wider range of conditions has been encountered in the metal mines of the United States. In addition to effects from dusts of various descriptions, and degrees of harmfulness, the health, safety and efficiency of our metal miners are, in places, seriously affected by heat, humidity, gases, and movement of air. A summary of the bureau's investigations, with a bibliography on the subject, is given in Serial 2374, which may be obtained from the Bureau of Mines, Washington, D. C.

The High Rate of Tuberculosis in Industry*

By FREDERIC S. KELLOGG, M.D., PITTSBURGH, PA.

IMPROVEMENT in the treatment of tuberculosis has been so great in recent years and the fall in the mortality so marked that the impression is current that tuberculosis is another disease which has been brought practically under control, thus promoting a certain complacency regarding existing conditions and a sense of security which are wholly unwarranted.

While the fall in tuberculosis mortality is undoubtedly very marked, the figures from which these rates are computed are necessarily very large and, of course, include very diverse groups of people, some of which groups are so well cared for and their lives are passed under such favorable conditions that the mortality from tuberculosis in their case would be very low. And the favorable showing of such sheltered and fortunate groups offsets the much more unfavorable and even alarming conditions of others living and working under adverse circumstances. A study, therefore, of various groups of the population and of particular industries will show that the line of advance against tuberculosis is very irregular—in fact, that instead of advance many centers of retrogression exist.

A case in point is that of the granite workers in the state of Vermont. The mortality from tuberculosis in the general population had been reduced one-half in the last twenty years. The people of that state might have indulged in the complacent belief that tuberculosis was being brought under control, but for the remarkable fact that, though the mortality for the state at large was reduced by one-half, the mortality among the granite workers had increased three fold. After a very extensive study of health conditions among the granite cutters the interest of the members of the Granite Cutters Union was enlisted and the men voted to assess themselves one dollar each to pay for necessary x-ray work. As a result of these studies the increasing and alarming mortality rate in this industry was shown to be due to the increasing use of pneumatic tools for cutting granite, a process which produces a fine dust, very harmful to the lungs, the deleterious effects of which, however, were

not observed for ten years, and the maximum effect not produced for twenty years, when the mortality went up very rapidly.

The case of these granite cutters is especially instructive in bringing out the great advantage gained by particular industries in having medical supervision and medical investigation. It has even greater significance in proving the fallacy of believing that the favorable showing for the state at large in reference to tuberculosis necessarily extended to all the industries of the state, the granite cutters included. The bad and dangerous trades were hiding behind the good record of a large population.

It has been well pointed out by Dr. Frederick L. Hoffman, the vice-president of the Prudential Life Insurance Co. who made the report¹ of this investigation, that there is urgent need for similar work in other industries. Only in this way will the hazards peculiar to certain industries be eliminated and conditions fraught with danger both to the employees and to the public be corrected.

Study Trades Separately

Statistics as to the morbidity or mortality from tuberculosis of the whole population of a state or of a city, do not give a correct idea of the tuberculosis rate in any given industry or among industrial workers as a whole. Some estimate or survey of the individual industries is called for. There are two ways in which such an estimate may be secured. The morbidity from the mortality found in any group of people may be determined by making use of the Framingham factor, ratio of ten active cases to one death from tuberculosis. The estimates given in this paper, with the single exception to be noted later, have been so determined; the tuberculosis mortality rate has been multiplied by ten, which is considered conservative. The only other way by which we can find out how many cases of tuberculosis exist in any particular industry is to make a complete study of that group. The mere recital of the number of cases of tuberculosis found in any industry is not very illuminating and does not convey any real information unless we have been accustomed to comparing figures as

to the morbidity of various diseases. A better idea as to the significance of such figures can be secured by comparing them with the figures for the morbidity of some other diseases with which we are quite familiar.

Dr. R. G. Burns² has submitted some interesting figures showing the morbidity in Pittsburgh from some of the most common infectious fevers: The morbidity per 100,000 persons in 1921 for scarlet fever was 288.6; diphtheria, 271; and measles, 317. In the last ten years the highest morbidity in this group is recorded for measles in 1920, when the incidence was 1,627.6.

It is instructive in this connection to consider the figures also for the morbidity from typhoid fever, a disease which was a scourge in Pittsburgh for so many years. The morbidity from typhoid fever in 1907, before the installation of filtration plant, was 1,119.2; in 1908, after installation of filtration plant, but without chlorination, the rate was 351.6; a rate which in 1912, with both filtration and chlorination, was reduced to 78.2, and in 1921 to 41.5.

To compare these figures with the morbidity for tuberculosis: The mortality rate per 100,000 population for the whole city of Pittsburgh for the two years 1920-1921 was 87.5. Estimated from this the morbidity for the same period was 875. (It may be said that the record of Pittsburgh for tuberculosis is much better than that of many other cities that might be mentioned. These figures will enable a better understanding of the morbidity from tuberculosis in some of the special industries of Pittsburgh. The figures, stated in all cases per 100,000 population are estimated from data contained in a study made of this subject by Dr. H. T. Brown³ of the Tuberculosis League Hospital. Some of the industries noted (Table I) have only a small number of employees engaged but the morbidity has been stated per 100,000 to make them comparable with other diseases. An estimate⁴ of the morbidity from tuberculosis among the employees of a large department store⁵ was secured by actual examination and study of 1,210 members of that group. Forty-two were found to have tuberculosis, the

diagnosis being confirmed by the sanitarium in each case. In addition to the forty-two cases positively diagnosed seventy-three employees, many presenting active symptoms of tuberculosis, left the service of the company before their cases were studied and the diagnosis completed. The figures given have been estimated only from the cases in which a positive diagnosis was made, which actually does not fully represent the incidence of tuberculosis in that group. It would be safe to say that the morbidity of department store employees is over four thousand per 100,000 employees.

Real Conditions Observed

It will be seen by a study of these figures that the actual morbidity from tuberculosis among the various industries of Pittsburgh has been obscured by the favorable reports given for the whole population. An immense amount of work must be done before there can be any real control of tuberculosis among the working people of Pittsburgh. If the health of these workers could be so safeguarded that tuberculosis would occur no more frequently in this group than in the general population the showing for tuberculosis in the city would be markedly improved and a great advance made toward the control of the disease. Any real advance in the struggle against tuberculosis must be effected by systematic medical care directed toward these congested and dangerous centers.

Special interest attaches to the discussion of this subject at the present time as labor leaders are advocating sickness insurance as a method of taking care of the sick in industry. With-

out discussing the question of sickness insurance, it certainly is incumbent upon us to devise and put into operation better and more effective means for taking care of the sick in industry. If we are to eliminate tuberculosis from industry we cannot afford to neglect any sickness or defect found in an employee. If a man is broken down in health from any cause he must receive adequate treatment; otherwise, any undue amount of exposure may develop tuberculosis whether at the time of our examination the worker shows an active lesion or not. An efficient medical service, therefore, assumes the task not only of detecting disease among the employees but sees that the sick or disabled employees receive adequate treatment, that follow-up treatment is assured, and complete rehabilitation of the sick employee effected.

Little Is Being Done

Various methods have been used for the care of the sick in industry, or at least to rid the industry of the burden of so much sickness. The most common, the routine physical examination of applicants for positions, has aroused great hostility from labor organizations. If the medical service stops with this initial examination certainly little has been done for the employee and it seems that the examination is designed rather to exclude the defective employee from service than to do anything for his rehabilitation. Diagnostic clinics are in use both in some large plants and also under the direction of some state governments, as in New York state.

A scientific diagnosis is an excellent thing and is a necessary beginning but does not insure adequate treatment. If the full benefit of the scientific diagnosis is to be secured and the patient receive proper treatment there must also be some effective system for follow-up work. In my experience⁶ it was found that of more than a thousand cases who had received a thorough examination and a careful diagnosis only six per cent were impelled by the scientific diagnosis to receive adequate treatment.

Protection of some insurance or disability fund is usually the reason and the sole aim of the medical work done among employees. Physical examinations for this purpose are excellent things, but are hardly enough to control tuberculosis or to maintain the health of a group of employees. Of the 2,252 industrial plants said to be

operating in Pittsburgh only a small proportion have any system whatever of medical care of sick employees.

Greater care and interest in the condition of employees would be secured by some extension of the scope of operation of the quarantine laws to prevent the harboring of so much communicable disease in industrial establishments. Scattered cases of infectious diseases in the residential districts are reported and cared for, but persons suffering from tuberculosis and other infectious diseases are constantly found working in industrial plants, and there is no method by which they may be detected and reported. The author has seen in different industrial establishments active cases of scarlet fever, diphtheria, whooping cough, pneumonia, measles, erysipelas, active secondary syphilis, gonorrhea, impetigo contagiosa, scabies—as well as tuberculosis. Other contagious diseases appearing in the city are sure to be found also in these industrial establishments because, as a recent writer has said, they are the clearing houses of disease, the distributing centers from which cases are broadcasted throughout the community.

A parallel condition occurred a number of years ago during an outbreak of bubonic plague in New Orleans. The Public Health Service was called upon to control it. Suppose in such an emergency those health officers had said: "We will not interfere with anyone in the city. Business will go on as usual, but if any cases appear outside the city we will quarantine those cases." Yet that is about the procedure in reference to tuberculosis, syphilis, and other infectious diseases. Scattered cases in residential districts are reported and quarantined when necessary, but there is no means of detecting or controlling disease in the congested and dangerous industrial centers.

It is not right that men or women should have to risk life or health by being compelled to earn their living in contact with tuberculosis and other infectious diseases, but the fact remains that probably most of the 118,000 industrial workers of Pittsburgh are constantly exposed to disease in this way.

The solution of the question of the control of tuberculosis and of the sick in industry has been pointed out to us by experience in industrial surgery. Not a great many years ago industrial surgery was practised in a careless way and with poor results. Little interest was shown in the accidents and injuries occurring in indus-

try. The workmen's compensation law was enacted and the responsibility for accidents in mills and factories was definitely placed on the industry concerned. The accidents were a risk inherent in the business and, therefore, it was held to be unjust that the unfortunate victim should bear the full burden of the accident. When the burden was placed on the business as a part of the cost of production the industries placed their surgical work in the hands of highly trained men. A tremendous development of industrial surgery resulted with a vast improvement in the care of the injured in industry.

Now traumatisms are certainly not the only accidents of industry. A man who becomes infected with tuberculosis when compelled to work in daily contact with the disease is a victim of an accident also—an accident of industry. When one or two thousand men or more work together under one roof we know in advance that tuberculosis and all other infectious diseases will spread from that center. Such infections constitute a risk inherent in the business, as much so as any physical accidents that may occur in the course of the day's work. An army in the field loses more men by disease than from bullets. Accordingly, a medical staff is organized and disease is controlled. But our industrial army has no such supervision, and disease is not controlled. Often it is not even suspected.

Disease occurring in such masses of men is an accident inseparable from such organizations and the responsibility for their control rests upon the administration which brings them together, whether it is civil or military. Now there is, of course, a vast difference in the status of the individual in civil and military life and for that reason we could not expect, or wish, every industrial concern to undertake the medical treatment of their employees. But industry should safeguard its employees from the inevitable hazards of their occupation, whether the accidents are traumatisms or infections. Further, by taking advantage of the many medical agencies which already exist in our cities, sick employees may receive some adequate treatment. No sick employee should be compelled, or allowed, to work.

The burden of all of the accidents of industry should rest not upon the individual employee, but upon the industry and the cost of the control of disease among the workers should justly be added to the cost of production. In point of fact industry does

pay the cost in lowered efficiency, in loss of time, in poor workmanship, and the disputes and contentions of sick people. The question, therefore, is rather shall this cost be paid in the future as extravagantly and blindly as in the past.

When medical work is thoroughly organized in industry tuberculosis can and will be controlled. There will be immense betterment in the condition of the working people and the much feared cost will be transformed to enormous economic gains.

Eye Sight Conservation

AIDED by Federal and state officials, university professors, engineers, industrialists, and civic leaders, the Eye Sight Conservation Council of America has set in motion a movement for the observance of Eye Sight Conservation Day in the schools.

Recent surveys have revealed that defective vision among children and workers in the industries has caused enormous economic and physical losses. Authorities declare that these losses can be wiped out by proper and systematic application of the principles of eye hygiene.

With the cooperation, among other leaders, of James J. Davis, secretary of the United States Department of Labor, Guy A. Henry, general-director of the Eye Sight Conservation Council, is directing the campaign, which aims to accomplish savings in health and money by carrying the message "First Health, Then Wisdom" to every city and hamlet in the land where children are taught.

The Eye Sight Conservation Council is enlisting the assistance of state commissioners of education, and of county and district school superintendents. The object of an Eye Sight Conservation Day in schools is to discover the fact that a child has a defect of vision or symptoms of a defect, rather than to determine the degree of efficiency.

Leading universities are taking up eye conservation. Columbia was the first to make it a part of its regular summer school curriculum, and the results attained were so satisfactory that the course will be continued. The University of Chicago, New York University, Ohio State University, Teachers College, Columbia; and the College of the City of New York have, through members of their faculties, identified themselves with the movement. Other active participants are L. W. Wallace of Washington, executive secretary of the Federated American Engineering Societies; Dr. Morton G. Lloyd, chief of the Safety Section of the United States Bureau of Standards; John J. Tigert, United States Commissioner of Education;

Allan J. McLaughlin, United States Public Health Service; and Arthur L. Day, director of the Geophysical Laboratories of the Carnegie Institution, Washington.

The Hoover Committee on the Elimination of Waste in Industry stressed the importance of eye care, revealing heavy economic losses because of poor vision. Secretary of Labor Davis, in a statement issued by the Eye Sight Conservation Council, asserts that care of the eyes is a national duty.

"In my earlier life as a workman and in the course of my duties as Secretary of Labor, I have come to know something of the problem before the Eye Sight Conservation Council, particularly in its relation to men and women in industry," says Secretary Davis. "It is a problem in human service which in its solution will mean much to the whole service of America in life, economic prosperity and happiness.

"Sight is, paradoxically enough, the most highly prized and at the same time the most abused of the human senses. I am informed that of the forty million or more men and women who are gainfully employed in the United States, upwards of twenty-five million suffer from some form of defective vision which is capable of correction and which should be corrected. This is an astounding number, and its reduction to a minimum would plainly better the condition of these sufferers, increase their efficiency in industry, and generally benefit the nation. . . . Whatever can be done in the way of improving employment conditions in this respect will be of inestimable service to the man who labors."

A recent endowment received by the University of Glasgow enables the founding of a chair of public health which has heretofore been part of the department of medical jurisprudence. With the foundation a place has been given to teaching public health in a city of over one million, with a birth rate of 29.1, a death rate of 15.3, and infant mortality rate of 105.

Place of Government in Fatigue Elimination*

By DR. A. F. STANLEY KENT, FORMER DIRECTOR OF THE DEPARTMENT OF INDUSTRIAL ADMINISTRATION, COLLEGE OF TECHNOLOGY, MANCHESTER, ENGLAND.

FATIGUE investigations in Britain may be divided into three periods: (1) That of purely private enterprise; that of tentative government action; that of serious government action. One of the earliest investigators of industrial fatigue in England was Professor Pembrey, who approached the subject from the scientific side and endeavored to elaborate a test for the condition; but after a time he was discouraged by difficulties encountered. On the engineering and management side, Messrs. Mather & Platt of Manchester, carried out experiments in 1893 which showed that "*before breakfast*" work was extravagant and ought to be avoided, and the government later on introduced the 48 hour week into arsenals and dockyards, but, though results seemed decisive, no general alteration of hours followed.

My own attention was attracted to the subject early, my interest being especially stimulated by the proceedings of the international Congress on Hygiene and Demography held at Brussels in 1903, and at other places in subsequent years, and also by the writings of Taylor, and later of Gilbreth in America. While the work carried on in America dealt largely with the engineering and management sides, my own was especially directed towards the physiological aspects of the subject.

The period of private enterprise ended when in 1913 the Home Office, yielding to representations made by Dr. T. M. Legge, C.B.E., His Majesty's Medical Inspector of Factories, placed certain facilities at my disposal, and made a contribution towards the expenses of investigations I had in progress. Some of the results obtained are recorded in the government publications issued in 1915 (White Paper, Cd. 8056), and 1916 (Blue Book, Cd. 8335).

In September 1915 a body appointed by the Ministry of Munitions to superintend the health of workers in munition factories, and known as the health of munition workers committee, turned its attention to the subject, conferred with the Home Office, and decided to initiate investigations in national factories engaged in the manufacture of munitions of war. Some

of the results of these researches may be found in reports published at the time. Thus, for a period, two distinct sets of investigations subsidized by the government were in progress, one started before 1913 conducted by myself for the Home Office, and one began in 1915 conducted by Dr. H. M. Vernon for the Ministry of Munitions.

For a considerable time no further advance was possible, in spite of repeated efforts to extend the scope of the investigation and to place it upon a wider basis. Neither Dr. Vernon nor I had anything approaching an adequate staff and to obtain well authenticated results rapidly was impossible. Finally, however, in July, 1918, the Home Office, acting through the department of scientific and industrial research, and the medical research committee combined to appoint a committee (industrial fatigue research committee) with the following terms of reference:—"To consider and investigate the relations of the hours of labor and of other conditions of employment, including methods of work, to the production of fatigue, having regard both to industrial efficiency and to the preservation of health among the workers."

This body has now been in existence for about four years and has published a number of reports upon investigations undertaken to elucidate particular points of interest. It is unfortunate that while many of these are of considerable value, others have met with sharp criticism, especially from the engineering section of the press. At one time the continued existence of the committee appeared to be doubtful, but it has now been reconstituted, and with the advantage of close association with the medical research council, should have a useful future before it. It must be recollected that at the time of its appointment the number of persons in Britain who possessed any practical acquaintance with industrial fatigue was extremely small, while the magnitude of the task placed before it, and its unusual difficulty, made it almost impossible to avoid initial mistakes. Moreover, the facts which it has collected must always be of value, whether the original interpretations placed upon them are right or wrong.

The above is a short resumé of the part the British government is taking

in work relating to fatigue. Were I asked the question "What, in your opinion, should be the place of Government in Fatigue Elimination?"—my answer would be somewhat as follows:—

Government organization is admirably fitted for the collection of facts relating to the general conditions under which labor is performed—facts relating to ventilation, heating, illumination, hours of work, rest pauses, rates and systems of payment, accident incidence, and rates of output—and to make use of such facts as a guide in legislation. But government will always be at a disadvantage in investigating the human side of industry. The suspicion with which government interference is regarded makes this inevitable. Hence, the influence which, in a particular case, the worker's mental attitude has upon excessive labor turnover, fatigue, loss of time, and generally unsatisfactory conditions in a factory, is, to some extent, a closed book to the government inquirer, largely because of the formality with which a government inquiry is conducted. These intimate matters can only be investigated successfully by the private worker who is not patently connected with a government department.

But even in the private worker many unusual qualifications are necessary—a real understanding of, and sympathy with, the workers' condition, the capacity to become for a time one of them, to live as they live, to share their hardship, and, above all, to let them see that, rather than deeming himself their superior, he has mastered his lesson and thoroughly appreciates the dignity of the labor which they perform. Conditions may be different and men with such qualifications may be common in America. In England they are, in my experience, excessively rare.

Safety First cannot begin too early, in fact, the earlier it begins, the more certain and lasting are its effects. In addition to teaching kindergarten children to sit still, why not teach them to walk without bumping into one another? Why not have a traffic game to teach them the rules of the road? Why not play speedcop to inculcate a respect for law? This is practical Safety First

*Read before the Society of Industrial Engineers, New York City, October 18, 1922.

Record Keeping and Statistics

AT A conference for welfare supervisors, held at Balliol College, Oxford, England, September 15-20, 1922, H. M. Vernon, investigator for the Industrial Fatigue Research Board, delivered an address on Record Keeping and Statistics.¹

Many of Dr. Vernon's remarks are applicable to industrial medical and nursing procedures in this country. Excerpts from his speech follow:

I have frequently been offered statistical records which were practically useless for my purpose, or, in fact, for almost any purpose, because of small omissions which could easily have been remedied at the time the records were made, if it had been anybody's business to superintend them. I hope, therefore, that I may be able to induce some of you to do what you can to supervise and improve such records as are already kept by your firms, and to initiate others when opportunity offers.

Labor Turnover

One of the most important of the subjects on which we specially desire accurate information is labor turnover, or industrial wastage. . . . Prof. Collis and Dr. Greenwood, in their book on the "Health of the Industrial Worker," quote an instance in which a number of establishments between them increased their total personnel from 39,000 to 47,000 in the course of a year (1912), or by eight thousand persons. To effect this increase no less than 44,000 persons were engaged, or five and one-half times as many as were kept in employment. This turnover is an exceptionally large one, but arguing from all the available information, the authors conclude that on an average the labor turnover in our factories and workshops is about 100 per cent a year, or that on an average each industrial worker changes his or her place of work once a year. The cost of engaging a fresh worker is very considerable, both to the employer and the employee. It may take weeks or months before the fresh worker learns his job and attains a good output, and during the learning period he is lowering the productive power of expensive plant and machinery. . . .

If this question is investigated, as it needs to be, I ask you to do it methodically, and obtain numerical details. The value of your inquiry will be greatly enhanced if you can get definite information as to the percentage labor turnover, for then you will be able to compare it from month to month and year to year, and if it shows a sudden and unexpected rise at any time, you would naturally endeavor to determine the cause and find a remedy. Again, if you find that the wastage at the factory to which you are attached is greater

than that observed at other and similar factories, you would endeavor to track down the reasons, and if you succeeded, to bring them to the notice of the management. If, on the other hand, the wastage at your factory is less than elsewhere, it would serve as a legitimate source of pride.

Lost Time Records

Even more important than the question of labor turnover is that of the health of the workers in the factory, and it is the main duty of the supervisor to do what he can to maintain and improve the health of the workers under his charge. . . . I have found huge firms spending hundreds of thousands of pounds a year in wages, who have not troubled to keep any lost time records whatever. And yet the keeping of such records is a comparatively simple matter. The timekeepers necessarily have to note down the timekeeping of all the employees, for the purposes of wage payment, and it would give them very little more trouble to keep permanent records of these times, in a suitable form for tabulation, than to throw them aside after each week, as they usually do at present. . . .

Disablement from Accidents

One of the chief causes of lost time in some industries is chargeable to accidents and injuries, and I am sure that all supervisors must take a considerable interest in this class of disablement, and be desirous of doing what they can to diminish it. Thanks to the rapid spread of the 'safety first' movement, increasing importance is being attached to the prevention of accidents, and supervisors can often do a great deal towards fostering the movement. In some of our largest factories special safety inspectors have been appointed, who give their whole time to accident prevention, but as far as I am aware, such inspectors are quite exceptional. In the absence of an inspector, what can a supervisor do? First, he can see that a proper record is kept of all accidents treated at the surgery. At some factories only the more severe accidents which have to be reported to the Home Office are noted. This is a pity, for much useful information can be obtained from a statistical study of the minor accidents treated. . . .

Factory Conditions

One of the numerous duties which supervisors may be called upon to undertake is to see that, so far as possible, the workshop conditions are conducive to the maximum degree of health and efficiency in the workers. No more important duty can be laid upon you, for it is to be remembered that, so far as waking hours are concerned, many of our industrial workers pass nearly half of their lives in the workshops. . . . Take, first, the much debated question of temperature. What is the most suitable temperature to aim at in our workshops? There is no generally accepted scale,

but probably most authorities would consider that a temperature of 60 to 65 degrees Fahrenheit is most suitable for workers engaged in fairly active work, whilst heavy manual workers should, as far as possible, have a distinctly lower one, say 50 to 60 degrees. In order that these temperature conditions may be observed, thermometers ought to be installed in all the workshops and read at regular intervals. If the readings are noted down in a book, it will probably be found that in some of the shops the temperatures frequently fall below or above the agreed scale, and in that case remedial measures should be taken. Also, if complaints are made by the workers records will show how far they are justifiable.

No less important than the temperature of a workshop is the state of its ventilation. Thanks largely to the investigations of Dr. Leonard Hill, we have in recent years come to recognize much more fully than in the past the effects of good ventilation on health and efficiency. Good ventilation consists, not so much in fresh air as in *moving* air. Stagnant air, however pure, is depressing and relaxing, and fails entirely to provide the stimulating effect of cool air in gentle motion. Hence the supervisor ought to do what he can to promote increased ventilation by opening windows and ventilators in workshops. A not inconsiderable number of workers prefer a stuffy atmosphere, and they enforce their desires on the others by shutting up the windows whenever they can. . . .

The more data you can collect and analyze, provided it is done intelligently, the greater will be your value in promoting the health and efficiency of the workers under your charge. Please do not think for a moment that you should neglect the more human and personal side of your work, or that you should try to carry it out on mathematical principles. All I wish to emphasize is that some sides of your multifarious duties do lend themselves to exact statistical treatment, and to suggest that you should develop this side whenever opportunity of doing so presents itself.

Bibliography on Hygiene of Industry

The *International Labour Review*, beginning with the May number, is publishing bibliographical notes on industrial hygiene that promise to be of great utility to everyone interested in industrial hygiene and allied subjects. They bring together papers and articles from foreign periodicals not available to average readers on industrial medical material under such main headings as hygiene and health in trades and occupations, hygiene and health of the workers, and industrial physiology and pathology.

¹Report of Lecture Conference, Balliol College, Oxford, England, September 15-20, 1922. The Industrial Welfare Society, 51 Palace Street, Westminster, S.W.1.

Human Factors in Accident

ACCIDENT rate in any particular industry is dependent alike on management, foreman, and worker. Where the authorities are indifferent to safety conditions accidents are high; where they make a concerted effort to prevent accident the rate decreases. The place of the foreman and the worker, the human factors in causing and preventing accident, is set forth by Lucian Chaney in U. S. Bureau of Labor Statistics Bulletin No. 298 entitled "Causes and Prevention of Accidents in the Iron and Steel Industry, 1910-1919," issued by the Government Printing Office, June, 1922.

The foreman can be of great value in accident prevention. Accident reduction bonuses offered to foreman spur them to greater care, and statistics show that where this plan is active accidents have decreased markedly. This superiority of the bonus group in accident reduction is due mainly to two causes,—(1) that the bonus group has a slightly superior physical condition and might be expected therefore to have lower severity rates; and (2) in the bonus plants there has existed since 1913 a bonus to the foreman for accident reduction.

The bonus system has the advantages of making the foreman realize that the company means business; it causes them to choose their men with an eye to physical fitness for the job; to instruct them in safety methods, and to associate a new man with an experienced worker. It also causes them, because of penalties imposed for undue absence of workers, to take an interest in the injured worker's quick return to the job. While this interest sometimes leads to a friendly relationship between foreman and worker again it leads to abuses such as returning an injured man too soon or making room for him at some other job at which he was not needed.

Though the foreman can, in large measure, reduce the accident rate especially when given the incentive of a bonus, a great portion of the safety of the worker rests on himself. Certain influences, such as youth, inexperience, unfavorable bodily conditions, illness, and fatigue increase minor accidents while the more serious accidents are usually caused by structural defect in the machinery. Statistics kept in a large steel plant from January to May, 1916, of the relation of accidents to the experience

of the worker indicate a rapid decline with increased experience. For those who had been employed six months or less the frequency rate was 37.1 cases per 1,000,000 hours' exposure; this dropped to 34.8 cases for those with six months' to one year's experience; the rate thereafter declined very rapidly and among those who had been employed more than fifteen years no accidents occurred during the period covered.

Other factors in increasing accident frequency were periods of business activity resulting in the speeding up of production and the taking on of

many new workers; geographic location making some cities more dependent on immigrant, non-English speaking labor; night work with insufficient lighting affording little protection; and the use of alcohol by some night workers just before coming on the job.

Records kept of production by hours in nine mills of a steel plant from September, 1912 to April, 1913, showed that contrary to the theory that fatigue should decrease output and increase accident, the reverse was found to be true, and in the hours when fatigue was usually considered to be strongest the greatest production was accomplished and the fewest accidents occurred.

Status of Working Women

THE 1920 census revealed the fact that one-fifth of all the women in the United States, or 8,549,511 are bread-winners. Questions which immediately arose were what percentage of these women are married and have small children dependent on their care, what percentage live at home, what percentage are single,—in other words what is the family status of these millions of women workers.

To determine on a small scale the family status of the working women of the country the Woman's Bureau took as typical Passaic, N. J., with its 10,000 women workers, four-fifths working outside the home.

Study showed that one-half of these women were or had been married; that nearly three-fourths of the married or once-married women breadwinners were mothers; that more than one-half of the mothers were working outside the home; and that of the 1,800 mothers working outside the home, over nine hundred had children under five years of age.

In answer to the question as to what care was provided for the children of these working mothers, the Woman's Bureau took one thousand addresses of women breadwinners living in Passaic who had small children. Agents were commissioned to follow up the addresses, establishing the identity of the occupants of the houses with the occupants living there at the time of the census enumeration.

The facts challenging attention in the results were: (1) That over one-fifth of the mothers worked at night, caring for the children in the intervals between indispensable rest taken during the day; (2) that near-

ly one-fifth left children with neighbors, landladies, or boarders; (3) that another fifth left children with mother's or father's relatives, about one-fourth of such relatives living outside the homes; (4) that over one-tenth of the mothers going out to work left the children at home to the care of husbands who were night workers, unemployed, or working at home; (5) that more than one-fifth left children virtually without care in the home. Eighty-two of these mothers, having children of school age, were assured that for part of the working-day at least the young were safe. The others had children below school age—some under 5—who had no care at all or only that given by children 14 years of age and under; (6) that but 25 mothers out of 522 left children in the care of paid custodians.

Turning to the single women breadwinners as pictured by the data assembled from the census schedules collected in Passaic in 1920, outlines of important features are impressively clear. The most cheerful phase of the picture is the large proportion—41 per cent—who were living in normal families where the fathers were breadwinners and the mothers were home custodians.

Nearly half of the single women breadwinners (women who were without male assistance in their families or women living independent of their families) apparently had sharply defined responsibilities for personal or family support.

Dr. Edward Martin has resigned as Pennsylvania state health commissioner after four years' service.

Interesting the Insured in His Health

A system of life, health, and accident insurance together with optional physical examinations has succeeded in interesting the employees of the Fred T. Ley & Co., Inc., of Springfield, Mass., in matters of personal health to their own physical betterment and the financial gain of the company.

The management inaugurated the scheme now in operation on the belief that if the man paid part of the expense they would be interested in seeing that they got some return for their money. On this principle the company offered to pay half the expense of the insurance system. The men are divided into three classes: those earning \$1,200 a year or less pay twenty-five cents a week for which they receive \$1,000 life insurance, ten dollars a week health and accident insurance for twenty-six weeks, and the physical examination services of the Life Extension Institute; those earning \$1,200 to \$2,500 a year pay fifty cents a week for which they receive \$2,000 life insurance, twenty dollars a week health and accident insurance for twenty-six weeks, and the privilege of periodic physical examination services; and those earning \$2,500 a year or more pay seventy-five cents a week for which they receive \$3,000 life insurance, thirty dollars a week health and accident insurance for twenty-six weeks, and the physical examination services of the Life Extension Institute. Additional insurance is allowed in recognition of length of service.

The entire scheme is handled through a mutual benefit association called the Loyale Club. The company had been getting a 20 per cent dividend on their group insurance for some years previous on an old system of group insurance. The management persuaded the insurance company to agree to increase this proportionally if their experience with the Fred T. Ley & Co., Inc. was better than their general average. They then told the Loyale Club that the dividends would be given to the club and a dividend of \$3,200 was a sufficient amount of money to induce the four hundred members of the club to try to earn it. This developed widespread interest in the annual physical examinations and the concerted effort to keep the whole force in the best physical condition.

The management further induced the insurance company to allow a committee of employees to decide when a person was entitled to com-

pensation. Insurance companies have found no way of compelling an employee to return to work, when they are satisfied he should, without antagonizing the rest of the men, but as soon as the men themselves were financially interested in having a man back at work they would not stand for any malingering.

The periodic physical examination is an important part of the scheme. While the results of the examinations are confidential between the individual and the medical examiner, the individuals seem to be perfectly willing to discuss their cases with the secretary of the club, and action is usually secured on the recommendations of the examining physician.

Anthrax Conference in London

A meeting of the International Advisory Committee on the Prevention of Anthrax, a committee made up of delegates from England, India, Australia, Italy, Sweden, Germany, France, Union of South Africa, and Belgium met in London on December 5. This body, which reports to the International Labor Office of the League of Nations, has for its principal object the study of methods of disinfecting wool, hides, hair, and similar products so as to protect workmen from the danger of infection with anthrax.

England has been particularly active in taking steps to eliminate the danger of infection of workmen in wool-handling establishments, and the committee agreed that for wool the English method seems to be effective.

The best figures available show that in the eight years up to and including 1917 there were only 222 deaths of humans from anthrax in the United States. Of these only about twenty-five, or 30 per cent, were of industrial workers. About 20 per cent of the deaths during this period were of farmers who became infected in most cases as a result of skinning animals that died on the farms.

Now and then stories have been published of cases of anthrax that have been contracted as a result of infected shaving brushes made of horse hair. Brush manufacturers in this country some time ago agreed to use no more horse hair in the manufacture of brushes of this kind.

The United States imports ten times more crude opium than Germany, France, and Italy together. It is estimated there are 5,000,000 drug addicts in the country today.

Industrial Standardization During 1922

The year 1922 saw greater activity in industrial standardization than any other year in the history of American industry.

One of the most far-reaching accomplishments of the year was the organization, on a working basis, of the Federal Specifications Board which develops and approves the specifications under which all government purchases are made.

The organization of Secretary Hoover's Division of Simplified Practice and its entrance into industrial field has had a highly stimulating effect on the industrial standardization movement. The distinction between the basis for this work and that of the American Engineering Standards Committee lies in the fact that the Division of Simplified Practice devotes itself particularly to that part of the field in which the decisions must be made on a non-technical basis.

More than 120 standardization undertakings now have an official status before the American Engineering Standards Committee, 43 of them having been initiated within the last year. Of the twenty-eight industrial standards developed and approved by the American Engineering Standards Committee since its organization in 1918, thirteen were approved within the past year. The efforts to develop national safety codes, which have been under way for a number of years, began for the first time to bear fruit. The following six safety codes, pointing the way to the elimination of the most serious classes of industrial accidents, were approved during the year: safety code for the use, care, and protection of abrasive wheels; safety code for the protection of industrial workers in foundries; safety code for power presses, foot and hand presses; national electrical safety code; safety code for the protection of heads and eyes of industrial workers. Specifications for the testing and use of permissible explosives have also been developed.

There are now national standardization bodies in fifteen foreign countries and a report recently received by the American Engineering Standards Committee indicates that plans are under way for the development of such work in each of the South American republics. The most recent of the national bodies is the Australian Engineering Standards Association, which held its first meeting on November 3.

Recent Compensation Decisions

By DOROTHY KETCHAM, DIRECTOR, SOCIAL SERVICE, UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

THE Industrial Accident Board of Massachusetts found that a deceased employee of the American Woolen Company received an injury arising out of and in the course of his employment. This injury was caused by the employee straining himself, while throwing cloth over what is known as "the perch," bringing on an umbilical hernia which became strangulated. A general condition of sepsis resulted therefrom which caused his death.

In the opinion of the Supreme Judicial Court of Massachusetts rendered November 29, 1922, "there was evidence that the employee on his return from work on December 27, complained of pain and stated that while lifting a piece of cloth 'it slipped and got away from him, that he felt something give in his abdomen, felt a sudden pain and had a lot of pain.' It was found that he had a dilated umbilical hernia. There was medical testimony tending to show that such hernias are caused by 'sudden lifting, sudden wrenching and falling,' that lifting the cloth in the manner described would be sufficient cause for the hernia; and that the employee's death on January 5, 1922, resulted from the hernia. On this evidence the board was fully warranted in finding that the fatal injury to the employee arose out of and in the course of his employment."—*Butler's Case 137 N. E. 175.*

THE Supreme Court of Michigan December 5, 1922, held that the conclusion of the Department of Labor and Industry that an employee's hernia was produced by an unusual strain when he was in an unusual position attempting to lift a heavy pulley and put on a heavy belt, which work required the help of another, was the result of an accident within the Workmen's Compensation Law and was justified by the evidence.—*Fibley v. Michigan Milling Company 190 N.W. 654.*

THE claimant's carpenter received on July 31, 1918, an injury on his right forearm through contact with a rusty nail. The injury became serious and later resulted in embarrassed heart action, known as endocarditis, which finally caused his death.

The Supreme Court of Pennsylvania

October 20, 1922, passed on the sufficiency of evidence to sustain the compensation award. "An examination of the testimony and especially that of the doctors, shows that the deceased, previous to the blood infection was a strong, healthy man, working regularly at his trade, and at no time before the accident had experienced symptoms of embarrassed heart action. The physicians who examined or treated him testified that the endocarditis from which he suffered was the result of the injury referred to. Without referring to the medical testimony in detail, we find it ample to sustain the finding."—*Guthrie v. Thomson-Starrett Company 118 Atl. 735.*

WHERE an employee accidentally suffered a slight bruise upon his shin, which was not sufficient of itself to cause disability, but which, three days later, owing to a diseased condition of his blood, broke open and formed an ulcer at the center of the bruise, it has been held by the Supreme Court of Nebraska, November 13, 1922, that the accident was the proximate cause of the disability which resulted in the existence of the ulcer, and further that such disability was caused by an accident arising out of the employment.

The evidence, according to the court, "establishes the fact that, at the time of the accident, appellee was suffering from syphilis, and a year later the disease was found to be in the tertiary stage, being localized at the point of injury to the leg, up to the time of which occurrence it had remained dormant, that an ulcer formed and had not entirely healed a year after the accident and appellee's disability arises from the ulcer in his leg. The district court allowed claimant for full disability up to the date of the decree and until such time as it is shown disability has ceased, and the employer has appealed."

The question for determination by the court was, what is the proximate cause of appellee's condition, the accidental injury to the leg or the disease? The appellant claimed that the condition was due solely to the disease and did not therefore arise out of the employment.

The court states, "We think the inference to be drawn from the testimony is that the primal cause of ap-

pellee's disability was the accident, aggravated by the disease from which he suffered. . . . The evidence does not suggest any cause for the existence of the ulcer at the precise place of the injury and so soon thereafter, other than the accident which occurred in the course of the employment. While it is true that the disease caused the wound to ulcerate the evidence is most persuasive that without the wound there would have been no ulceration. We conclude that the accident was at least in part the proximate cause of appellee's disability and the fact that his recovery was delayed by the existence of the disease will not prevent a full recovery. . . . It is generally held that the fact that a pre-existing disease contributed to the disability does not affect the right to compensation, provided the accident produces physical conditions which in connection with the disease bring about the disability. . . . The test to be applied is, did the employment develop the injury in a material degree? . . . In the case at bar it was not necessary, if indeed it was possible for appellee to show that a disease of the blood had been aggravated by a trauma, it was sufficient to show the trauma and resulting disability, though the latter was contributed to by the disease. . . .

We think the disability for which compensation was awarded arose out of and in the course of the employment, and that the decree below is right, and it is affirmed."—*F. H. Gilcrest Lumber Co. v. Rengler 190 N.W. 678.*

THE following decision of the Supreme Court of Michigan rendered November 2, 1922, is of importance to vocational officers and those associated with the scheme for industrial rehabilitation, in that it endorses lump sum payments by the industrial board in certain exceptional cases "where circumstances create a necessity therefore."

A lump sum payment may be awarded for compensable disability where circumstances create a necessity therefore as provided by the board's rules of procedure, though there is no agreement and no application for such payment.—*Thayer v. Berkey & Gay Furniture Co. 190 N.W. 231.*

A JAR or misstep which causes hemorrhage resulting in the loss of the eye is held an "accidental personal injury" within the compensation law.—*Winona Oil Company v. Smithson 209 Pac. 398.*

INSTITUTIONAL HEALTH

The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents

Modern Trends in the Health Care of Children*

Correct the Subnormal Standards That Have Produced Our Subnormal Children

BY HOMER FOLKS, PRESIDENT, NATIONAL CONFERENCE OF SOCIAL WORK, NEW YORK CITY.

THE first modern trend in children's work, using "modern" to mean the last ten or fifteen years, is a rather general recognition of the fact that social conditions change and, therefore, children's work must change or else become obsolete and out of touch, unadjusted to the community.

We used to think instinctively that poverty, distress, crime, neglect and orphanage were part of the natural order of things, like the currents of the ocean, the movement of the heavenly bodies, and the coming and going of winter and summer, and that every year brought not exactly a fixed, but a regular proportion of trouble and distress and poverty which had to be cared for, and all we had to do was elaborate our social machinery, agencies, and institutions to take care of that particular amount which existed in our community.

Now we all have come to see that the conditions and facts which produce orphanage, neglect, distress, and poverty are part of that complicated series of human affairs which we call civilization, that they are man-made, that man can change them, and that man is changing them. Perhaps the most striking instance of such change in our own field of child care is to be found in the cause of the organization of the very first child caring institution in America. It was established many years ago in New Orleans, an orphanage to take care of the children left orphans by an Indian massacre in Natchez, Miss. In-

dian massacres have not contributed largely to the population of orphanages for a good while, but that particular institution, organized to meet a particular need at a particular time, continued to exist for about one hundred fifty years. We have to change in the long run, as conditions change, but there are three different ways of doing it. One is to stand pat and await the coming of the big stick or something else that obliges us to change. Another is to keep our ears to the ground and change just as much as will keep us even with the current of popular change. A third, studies the trend and direction of social movements, which keeps one step ahead, which exercises some leadership and doesn't always merely follow.

Prevention That Prevents

The second trend is that children's work is a part of social work in general, that we can not think of it nor deal with it separately from other kinds of social work—that when we try to isolate it and deal with it by itself, we immediately begin to go wrong. An instance of that is workmen's compensation, which is something that seems in quite a different field from children, *i. e.*, the field of labor legislation.

Twenty-five years ago a city district committee of a charity organization nearly always had before it the case of the children and the wife whose husband was injured in an accident. That was a substantial demand on private charity. It is perfectly obvious now, of course, that the change in

that respect, the introduction of a modern workmen's compensation act, makes a vast change in the number of children who have to receive charity either in their homes or elsewhere.

The third change in the modern trend of children's work is that prevention is beginning to prevent! We are now beginning to get the benefit of the things which were undertaken in a preventive line fifteen and twenty years ago. It was just about twenty years ago that the movement for the prevention of tuberculosis was begun. I wonder if any of us can begin to understand the many ramifications of what has happened about tuberculosis in the last twenty years in our particular field of children's work. Unless we stop to think we do not realize that tuberculosis, which twenty years ago was the largest cause of death and which had taken away the parents of half of the children in our orphanages, has been reduced one-half.

What an enormous change that has made in the scope and kind of the children's work which we have to carry on! There is less demand for home relief where the father is sick with tuberculosis. The volume is reduced just one-half. The demand for widows' pensions, or whatever kind of relief is to be given widows, is similarly cut in half so far as tuberculosis is concerned. The number of children to be placed in institutions is greatly reduced and, another factor usually overlooked, the amount of juvenile delinquency is greatly reduced by the prevention of tuberculosis.

*Read before the Ohio Welfare Conference, Columbus, O., November 1, 1922.

One of the first studies the author made in social work was in juvenile reformatories as to how many had lost one or both parents, and it was plain then, as it has been ever since, that the loss of one parent is the factor which in many cases leads to delinquency.

The control of typhoid fever has a similar bearing. Every step taken by the health authorities—by the state and by the locality—in reducing causes of death is a step in the reduction of the work of the children's orphanages, of child adoption societies, of home finding societies and juvenile reformatories.

Benefits of Social Activity

We are beginning to get the benefit of prevention. The census of our juvenile reformatories in the state of New York is very much less than it was a few years ago. Some of them have closed substantial parts of their institutions; one or more are thinking of discontinuing the work entirely; one of our state reformatories for men has been closed, and all of them show a much reduced census.

Let us consider each of the four groups with which we deal in children's work and see how the volume and kind of work has been changed and is changing and is going to change still more by other forms of social welfare activity.

We have considered, first, the destitute children who are simply poor, whose parents cannot take care of them. Prevention of tuberculosis and other health work, workmen's compensation and, above all, the spread of widows' pensions and mothers' allowances has almost removed from consideration the subject of destitute children as related to other than their own home. There are many children to be provided for, but the White House Conference on Dependent Children in 1909 adopted the principle that children should never be removed from their home because of poverty alone. We are coming pretty close to the realization of that principle in actual practice.

As to neglected children, the second large group, there are two conflicting currents in different directions in regard to the volume. First, perhaps most of us at times, when we have read of some terrible case of cruelty and the rescue of some child from terrible maltreatment continued over a long time, have been very much distressed about it, and then we have seen the statistics of the numbers of children dealt with by societies and organizations, and conclude we have ob-

tained a somewhat erroneous impression of the volume of situations of that kind. As a matter of fact, only a very small percentage of the large number of children cared for by child caring organizations came from extreme instances of cruelty.

A foreign representative once studying child welfare work in New York had seen the pictures and reports of our humane society, of children beaten. Then he read how many thousand children they dealt with in the year. He said "Is it, then, that you have so many cruelties in America?" If he had read closely, he would have seen that about 95 per cent of those children were lost children, picked up and returned to their parents, and children dealt with for slight circumstances.

But, when we come to the actual neglect of children, we find that there are two main causes, two groups of cases. The first is that neglect which is the result of intemperance—long—continued intemperance. The second is that which is due to mental deficiency, a real mental lack or the beginning of a mental disease on the part of the parent. And, we are really making a good deal of progress in those two directions. The Eighteenth Amendment and our local laws are very greatly reducing the actual use of liquor by the bulk of the people, which must result in a marked reduction in the number of cases of that extreme neglect of children which leads to their removal from their homes.

Through mental clinics and the examination of school children, we are finding our cases of mental disorder and mental deficiency at an earlier period and, instead of removing them from their homes after they have become delinquent or for other causes, we may look forward to finding them at an earlier date, caring for them as they should be cared for, and then they themselves will not be giving birth later to children whom they will subsequently neglect.

On the other hand, we must recognize this fact: We have never discovered in this country all the cases of neglect of children. We have only hit on one here or there when some peculiar fact or circumstance brought it to light. With all our humane societies, we have never sought them and discovered them, and whenever a new county agency really seriously follows up all the cases, we have found always a much larger number of instances than we had before thought existed.

So, we have an actually diminish-

ing volume of neglect, but an increasing proportion which comes to our attention and is dealt with, and we deal with it in a somewhat wiser way. One used to read of this or that terrible case of neglect of a child, look at the picture of the child and read the account of the trial, and then at the end, with what a sigh of relief and satisfaction read that the child was taken away from those parents and committed to some institution. That is where the average citizen stopped. Now we are looking it up a little to see how many of those, going in at the front door in some private home or institution, before long go out of the back door and back into that very home, that very set of circumstances from which he had been rescued not so very long before. It certainly has been true in our state that the great volume of children rescued from neglect and cruelty have been supported for a time at public expense, the parents being relieved of that burden, and then the great majority have found their way back to those very same homes and parents when they were able to work and turn their earnings in to those same parents. That is not a very effective way of dealing with neglect. Now we are finding that a great many of those cases were not so bad really as we thought they were, and that it is possible by probation, by home visitation, by close supervision, by advice, sometimes by material help so to change circumstances in those homes that the children need not be taken away at all. That fact bears on the diminution of children who must be cared for away from their homes.

Delinquency Is Reduced

It certainly is true there are many, many factors tending to reduce child delinquency. We have but half as many orphans, and that is a great factor. We have more adequate widows' relief. We thought in New York City a very few years ago when we were spending about three or four hundred thousand dollars in widows' relief that we were doing a good job, but we now consider that the reduction in our juvenile delinquency is not unrelated to the fact that we are now spending three and a half million dollars a year in the City of New York to assist widows in the care of their children in their own homes.

There is also a distinctly new trend in regard to crippled children, those most unfortunate little creatures, and this new trend is that they should be taken care of, cured, if possible, or their conditions improved.

The first hospital for crippled children was established by the father of Theodore Roosevelt, as one may read in the book by his sister, Mrs. Robinson. Fifty years ago we had two or three hospitals for crippled children and they were equal to the demand. But, that was just the trouble. Neither the crippled children nor their parents were in the way of demanding. We do not stop to think how far above the workingman's family these agencies are and how little he knows how to go about it, and the mere fact he does not know what to do means he does nothing in a great many cases.

Two things have sunk in very deeply, that the hospitals, even where equal to the demand, did not mean that all crippled children were being cured. We had an epidemic of infantile paralysis and after that was over, we established a series of clinics all over the state with the best physicians and surgeons and nurses we could get. To those clinics there came large numbers of crippled children, and from one-half to a one-third of those children were crippled not in the recent epidemic, but in an earlier epidemic, but had gone unnoticed and uncared for all those years.

Mental Field Complicated

What is the modern trend in regard to the care of mentally defective children? Eight or ten years ago that could have been answered very simply by mathematics, by an equation. We thought we knew about how many feeble-minded children there were. We reckoned how many we had beds for in our custodial institutions and how many we were building a year and we could figure by mathematics our exact needs—so much a year for so long a time would bring us to the time when we would have them all in the institutions provided. It was a question of bricks and mortar. Whatever the trend of children's work for the mentally deficient, it certainly is not as simple as that now. We all recognize it is a great deal more complicated, difficult, diversified and complex.

To enumerate very sketchily, what are some of the trends of the care of the mentally deficient children? The first one is a very interesting instance of the interplay of these different social factors in considering one with the other. You know about the Shepard-Towner bill. It is doubtful if the advocates of that bill had any idea they were dealing with mental hygiene, but they were, because a definite and appreciable proportion of

mental disturbance and mental defect is based upon complications and accidents attending childbirth, and really adequate maternal care would reduce the mental disturbance.

The pre-school age of children, too, is one to which we have not connected any thought of mental deficiency or mental hygiene, and yet, as somebody has said, if children in those early years are not learning to read, they are certainly learning the A-B-C of human life and if they get wrong impressions, prejudices, wrong emotional reactions at that time, things are started that may be very serious later on. In Boston great benefit resulted from the establishment of habit clinics, for the purpose of straightening out bad habits which get started, and which left unchecked would mean a more pronounced mental disturbance or mental departure from the normal.

The tuberculosis authorities have been telling us for a long time, that all of us have a little tuberculosis all the time. We may apply that to a larger field and wonder if we are not a little bit crazy at times, more sometimes than others, and some of us more than others, perhaps. We are all the least bit feeble-minded. Again, some of us quite a lot, and some not so much, but most of us depart sufficiently from a real mental poise, from a sound emotional life, to affect our usefulness as citizens and disturb our happiness as individuals. The mental hygiene which can be taught in those early years, the sound teaching, the correction of minor departures in early life, will make the next generation more sane, more sound, and better balanced, make better citizens and better parents, and will increase the sum total of human happiness and well being.

Then we come to the schools, public and others. The one public governmental agency which practically reaches all the children is our schools. The establishment of the universal public school system was the most radical, far reaching, revolutionary thing that ever happened in the history of any country, and certain it is around the public school system utilizing the opportunity to deal with all of the children, that our great opportunities in mental hygiene lie. When we set about really finding all the children in schools who are different and odd and peculiar, and secure instruction and care more suited to their particular needs, and when we make their needs the occasion to bring the parents into the school and talk with them about the origin and

the evidences of this trouble at home and how it may be corrected, and when we have the teachers going into the homes, then we shall have taken steps that will serve enormously in reducing the volume of mental disturbance which is now such a drain on the economic efficiency of the country.

Without tracing through the different things affecting the mental hygiene of children, it is merely suggested that there, again, is a piece of general work, attending to all the children in the community, of the greatest importance in our specialized problem of dealing with these destitute, neglected, and delinquent children. And dealing with these particular classes of children, whether we like it or not, is but another means of reducing the general problem of child caring institutions.

All that gross total of taking away children from their homes is a diminishing factor in social welfare. We need not disagree as much now about the best way to care for the child outside of the home for there is not going to be as much to do. Instead a much greater volume of work will be undertaken for the supervision of all the children in the community.

Specific Lines of Attack

We have just recently seen that if bad teeth diminish the effectiveness of an army, they diminish the effectiveness of the army at home in civilian clothes just as much. But, in view of the impossibility of providing dentists enough to fill all the decayed teeth now harbored in neglected mouths, the only real remedy is to begin earlier with services in dental hygiene.

The war likewise is responsible for the present improved program for the treatment of undernourished children. At first the remedy was sought through providing school lunches. Then it was found that the homes of the children disclosed many things beside insufficient or unsuitable food that have to do with the habits and health of the child, and that handling malnutrition involves dealing with the entire health of the child. Just as we began to think we had come to an understanding of the subject of malnutrition, Dr. Fifebacker of New York City revolutionized the matter by stating the subject was not one of correcting malnutrition, but the prevention of malnutrition. Thus the subject was brought back to a basis of education—the public health education of the child in the school, and, through the school, the education of

the parents. That really is the great hope of the future.

It is a comprehensive program—dealing with this subnormal standard of living—that can be approached in three ways: (1) It can be regarded as a matter of relief, which is the hardest way to get at it. (2) It can be dealt with as a matter of educa-

tion, which is much easier. (3) Or, it can be handled as a matter of health, which is still easier, as everybody believes in health. By combining health with education—health education—we may hope finally to discover a short and really effectual way of remedying the prevalent low standards of living.

New Public Baths for Harlem

NEW YORK City will expend \$170,000 on the new public bathhouse to be erected soon at 134th street between Fifth and Lenox avenues announces Julius Miller, president of Manhattan borough. Though the baths are in the center of the negro district they will be open to both races.

The building will contain 170 showers, a three story gymnasium, and roof garden. The interior will be finished with materials immune from vapors arising from showers. A control of water temperature will be instituted in the boiler rooms so that it will be impossible for any bather to suffer injury by inadvertently turning on the hot instead of cold water.

Arrangement has also been made to shut off the water for each shower from the boiler room, this to prevent bathers from lingering and keeping others waiting. Devices to insure against theft are also being worked out according to Mr. Miller.

The building from the street level will be four stories. Office and wait-

ing rooms will occupy the front of the first floor, the rear of which will be divided into two sections, one for men and one for women, each equipped with twenty-nine showers and three bathtubs. Forty-four showers each for the men's and women's sections will occupy the entire second floor.

Two locker rooms having nine showers each with space for clothing lockers will occupy the front of the third floor. The rear part of the floor will be the gymnasium 53x64 feet with a twenty-five foot ceiling, extending through the fourth floor. At the level of the fourth floor an indoor track will be built in the form of a balcony around the gymnasium, the width of the track to be seven feet and the distance around it 175 feet.

Locker rooms equipped with three showers will be installed in the front of the fourth floor.

The playground on the roof will be used as a community center. It will have an open air area of 5,200 square feet.

The exterior of the building will be of brick with granite base and limestone trimmings. The interior walls of the upper part of the building will be of light colored pressed brick, the ceilings of Guastovine tile. Floors of entrance lobby, shower room aisles, and lavatories will be of white hexagonal tile while the roof will be finished in red promenade brick. Floors of showers and dressing compartments, and locker rooms are to be of cement and floors of the gymnasium and running track of wood. Partitions for shower and dressing compartments will be of white Italian marble.

A Standard for Condensed Milk

In the Milk and Dairies (Amendment) Bill, recently given its second reading in the House of Commons, effort is made to establish the standard of food value. Dr. W. J. Howarth quoted the impression that condensed milk now imported from abroad is not on the whole of such good quality as prior to the war. Analysis recently made by the city analyst shows that the percentage of fat in thirteen samples of sweetened whole-milk varied from 6.45 to 9.35; in two unsweetened whole-milk samples the corresponding figures were 7.7 and 8.2, these figures comparing unfavorably with tests made in 1911. Dr. Howarth's calculations indicate that the amount of milk fat in ounces purchasable by a unit of one hundred pence in the sweetened whole-milk supplied in tins varied between the wide limits of 9.02 and 16.42, a difference which can scarcely be held to result from differences in commercial methods in preparation and distribution.

The solution proposed is to require a standard of 9 per cent of milk fat to which manufacturers should work. One part of such condensed milk diluted with two parts of water would then give a fluid milk complying with the present milk-fat standard of raw milk. In common with other health officers, Dr. Howarth also asks that requirement be made that the label of skim milk should bear conspicuous display in contrasting colors of the statement that such milk is unfit for the food of infants.

Compulsory health insurance of all children attending the primary schools was ordered by a recent decree of the council of the Canton of Valais, Switzerland. The state will meet a part of the cost.

Roof garden of proposed new \$170,000 baths to be built at 35 West 134th Street, New York City.

An Ideal Out-Patient Service in Pediatrics

THE Section on Pediatrics of the Associated Out-Patient Clinics of New York, including a representative of the professional staff of each of thirty-seven pediatric clinics of the city, has, through the executive committee¹, been actively engaged in working out plans for aiding and improving out-patient service in pediatrics. The Section agreed that the professional staffs and governing authorities of the pediatric clinics would be stimulated by the existence of an approved standard and by comparison of existing clinics with this standard. As a first step, requirements for an out-patient service in pediatrics were formulated as printed below.

These were submitted in their first draft to various interested individuals for criticism and, after revision according to suggestions received, were finally adopted by the Section and by the general committee of the Associated Out-Patient Clinics. It was felt that in order to provide the maximum incentive to improvement, the standard should be set high. The outline herewith is, therefore, more or less ideal, but is believed to be capable of practical realization. The Associated Out-Patient Clinics, and in particular the committee responsible for drawing up these standards, invite the criticism and suggestion of all interested in out-patient service for children.

During the summer of 1922 the member clinics were visited, and their organization and methods compared with these standards. The survey showed that several clinics in New York City closely approximate the standards set by the Section; that others are conducting pediatric out-patient service of a superior grade; but that many clinics have unsolved problems of organization and management and that there are frequent failures to meet essential requirements. Both medical and administrative authorities of the institutions visited were usually much interested in their rating by these standards and many plans for improving service in order to meet the requirements are already under way.

Funds have also been pledged to the Associated Out-Patient Clinics by the Committee on Dispensary Devel-

opment of the United Hospital Fund to assist one or two selected clinics to improve their service so as to demonstrate, as nearly as possible, the working of an ideal pediatric clinic. It is hoped that some demonstration of this type may be under way in the near future.

The standards indicated set forth the principles of organization and procedure, the facilities and the equipment necessary for the satisfactory service of a pediatric out-patient department in the diagnosis and treatment of patients. It is felt that a pediatric clinic should also assume certain educational responsibilities: education in the prevention of disease through contact with the parents of patients (utilizing the waiting period for this purpose when possible); the provision of experience and training for practising physicians as well as for undergraduate and graduate students: organization for research into various pediatric problems; and the periodic measurement of the results of the clinic management of patients, to point the way towards improved methods.

Various general subjects—such as administration, organization, admission, fees, etc.—have not been considered in the formulation of these standards, as recommendations on these matters are formulated by the central executive committee of the Associated Out-Patient Clinics.

1. MEDICAL ORGANIZATION.

(A) It is desirable that there be a ward service in connection with every dispensary. Independent dispensaries should have close affiliation with some hospital, with interlocking staffs. (The standards herein outlined presuppose that there is a ward service in direct connection with the clinics.)

(B) The hospital and out-patient staff should constitute one organization. Every member of the staff should have some duties and responsibilities in the out-patient department. After a proper period of probation every member of the staff should have some ward duties and privileges. The entire staff should be encouraged to follow its cases admitted to the wards.

(C) The staff (1) should be assigned definite hours for attendance in the out-patient department. (2) The director and the senior staff should attend the out-patient department at least once a week at specified hours, for consultation. (3) A record of attendance should be kept and analyzed periodically. No physician should hold an appointment whose record of attendance is not satisfactory.

(D) The chief of clinic (1) should be of rank corresponding at least to

that of an assistant attending physician to the hospital. He should be responsible for maintaining the medical standards and should be in personal charge of the clinic work. He should assign the staff to cover the various sessions of the clinic and the special clinics. He should supervise diagnosis and treatment advised or instituted by juniors, and should submit necessary reports to the director of the service. (2) The chief of clinic should be present during the entire clinic hours of the day when he is on duty. (3) In large clinics some of the duties of the chief of clinic may be delegated to other members of the staff.

(E) The interns on service in the wards (1) should be definitely assigned to regular duties in the out-patient department. (2) To make out-patient as well as in-patient service possible, the number of interns on duty should be increased, if necessary.

(F) The medical staff (1) should be relieved as far as possible of all duties not directly concerned with the diagnosis and treatment of patients. (2) Trained assistance for performing the executive, social service, nursing, clerical and technical functions should be provided.

(G) Staff conference for the discussion of both ward and dispensary cases should be held at least once a month which all members of the pediatric department should be required to attend.

II. SOCIAL SERVICE.

The Social Service Section of the Associated Out-Patient Clinics has formulated general standards of organization and function of social service in clinics, only certain special points are included here.

(A) At least one social worker should be assigned to the pediatric clinic.

(B) The medical social worker should be invited to attend the staff conference.

(C) There should be provision for privacy for social service worker's interviews with patients.

III. SPACE, EQUIPMENT AND FACILITIES.

(A) There should be adequate rooms for examination and for teaching purposes, where teaching is done at clinic.

(B) There should be adequate cubicles for isolating contagious diseases.

(C) The services of (1) a modern laboratory and x-ray plant should be available. (2) There should be proper laboratory facilities for the immediate examination of and report on specimens of blood and urine, when necessary.

(D) Equipment should consist of: (1) Proper ventilation, plumbing and light; (2) walls and floors easily washed; (3) drinking water with paper cups; (4) facilities for heating bottles; (5) proper desk and chairs; (6) proper scales for infants and children; (7) measuring instruments; (8)

¹Executive Committee is constituted as follows: Roger H. Bennett, M.D., chairman; William P. St. Lawrence, M.D., vice-chairman; Drs. Murray Bass, Stafford McLean, Marshall C. Pease, Jr., Mark S. Reuben, Frank Howard Richardson, Louis C. Schroeder, and Charles Hendee Smith, Gertrude E. Sturges, M.D., Executive Secretary.

proper examining table; (9) proper light for nose, ear, throat and head work; (10) "reference blanks" for patients referred to other departments of the institution or to other institutions; (11) proper surgical instruments; (12) printed diet lists and printed hygienic instructions for children over two years; (13) educational material to supplement the verbal instruction for special diseases; (14) cover near entrance for perambulators is desirable.

IV. ADMISSION AND DISTRIBUTION OF PATIENTS.

(A) At least twenty minutes should be spent on the history examination and treatment of each new patient and as much time on old patients as the individual case may demand.

(B) A competent assistant, preferably paid, whose chief duty should be the segregation and isolation of contagious cases, should be present during all clinic hours.

(C) The patient should be treated by the same physician continuously except when referred to a special class.

(D) All cases should be admitted first to the general pediatric clinic for diagnosis. Suitable cases should be referred to special classes.

(E) It is desirable that the upper age limit for attendance at the pediatric clinic should be puberty with a maximum of fourteen years.

(F) As far as possible, visits should be made according to prearranged appointment. The details of organization will need to be modified to meet the possibilities of individual clinics.

V. STANDARDS FOR PHYSICAL EXAMINATION.

(A) Each child should have a complete physical examination on admission, younger children completely stripped, older children stripped to the waist (or completely if indicated), and receive such examination as is necessary on subsequent visits.

(B) All doubtful or unusual cases should be seen by the chief of clinic or consulting physician.

VI. STANDARD FOR TREATMENT.

(A) Where no infant milk station is maintained at the clinic, appropriate cooperation should be maintained with a department of health station.

(B) The clinic should cooperate with the schools, social agencies, day nurseries, etc., by the diagnosis and treatment of referred cases. It is desirable that cases should be referred only from a specified district mutually agreed upon and that, so far as possible, cases should be referred by appointment in such numbers and at such hours as may be of greatest mutual benefit.

(C) Close cooperation should be maintained with the agencies providing convalescent and country care.

(D) There should be facilities for consultation in all required specialties, including mental hygiene and dentistry.

(E) Special classes (1) for group treatment of cardiac disease, vaginitis, syphilis, malnutrition, asthma, etc.,

are highly desirable. When it is not feasible to form separate classes, equivalent care should be provided through the special management of cases or by reference to appropriate institutions. (2) It is desirable to group patients in classes according to age.

(F) The patient should receive written or printed instruction in addition to verbal directions, (instruction lists, diet lists, etc.)

(G) The amount of medicine dispensed should be sufficient to obviate the return of patients for medicine only.

(H) In case facilities for follow-up are limited, the chief of clinic should be responsible for designating the type of cases to be followed up.

VII. CONTENTS OF RECORDS.

(A) Ordinary identifying data and date of each clinic visit.

(B) Social data including: (1) Birthplace, (2) descent, (3) size and constitution of family, (4) income; and (5) family contacts with charitable and health agencies.

(C) Family history, including (1) history of epileptics or mental defectives; (2) mentality of parents; (3) exposure to tuberculosis or syphilis; and (4) chronological history of pregnancies.

(D) Birth history, including: (1) Period of gestation, (2) type of labor, (3) place of delivery, (4) birth weight; and (5) diseases and injuries of the new born.

(E) How long nursed and technic of nursing or, if artificially fed, detailed feeding history, arranged chronologically, and varying with age of child.

(F) Development history including date of sitting up, walking, teething and talking.

(G) Habits.

(H) Previous illness.

(I) Accidents and operations.

(J) History of present illness: (1) Duration and onset; (2) chief complaint; and (3) previous medical care.

(K) Physical examination:

(1) Measurements: Height; weight; head; chest; fontanel. Expected weight for age and height.

(2) General condition: Nutrition; skin.

(3) Deformities: Posture; head; thorax; spine; feet.

(4) Lymph nodes.

(5) Nervous system: Mentality; reflexes.

(6) Heart.

(7) Lungs.

(8) Abdomen: Liver; spleen; hernia.

(9) Genitals.

(10) Eyes.

(11) Ears.

(12) Nose—breathing.

(13) Mouth—teeth.

(14) Throat—tonsils.

(L) Diagnosis.—Tentative diagnosis should be recorded at the first visit and revised as the findings warrant.

(M) Treatment.—Treatment advised or instituted should be noted. Copy of instructions and advice, including details as to feeding and medication, should appear on the chart.

(N) Progress notes. — Progress

notes should be made at every subsequent visit.

(O) Date for return visit.—The date when physician wishes the patient to return should be noted at every visit.

(P) Laboratory notes.—The record of all laboratory work, x-ray and other special tests done for the patient should be incorporated with the medical history.

(Q) Record of medical social service.—At least a summary of all work done and information obtained by the medical social worker should be incorporated with the medical record.

(R) Signature.—All entries should be signed by the physician or other person making examination or report.

(S) The records of the in-patient and the out-patient should be unified as completely as possible.

VIII. STANDARD NOMENCLATURE.

Each pediatric service should formulate a standard nomenclature for use in the entire institution.

Public Health in Denmark

In Danish history of public health the year of 1921 was a record year, the rate of mortality being only 11 per 1,000. Out of a population of nearly 3,300,000 only 36,000 died. On the whole, public health in Denmark is standing very high. Danish statisticians boast that no other country has shown so low a death rate as that observed in Denmark last year.

The *Journal* of the American Statistical Society, however, claims an average of only 9 to 10 per 1,000 for New Zealand, a rate that in the age distribution standard of Sweden would average about 12 per 1,000.

Infant mortality in both Denmark and New Zealand is very low. Climate, virility of the race, and the comparative absence of large industrial populations are favorable factors in both countries.

In 1921, Denmark registered a considerable natural increase of population, births exceeding deaths by about 12 per 1,000.

Colonel Munson is working with Governor General Wood to bring about the passage of a bill laying the foundation for a countrywide system of hospitals in the Philippines. Of the forty-eight Provinces visited, twenty-eight lack hospitals, and in thirty-two nothing is done to preserve public health.

Dr. de Jesus, director of the Philippine health service, told members of the chamber that two-thirds of the total deaths in the island were due to preventable causes. Half the economic loss, he said, could be saved through installation of a modest hospital system.

Health Provisions of Antioch College

Balanced Diet and Exercise Keep Students in Good Trim

By GEORGE P. PAUL, M.D., DIRECTOR, DEPARTMENT OF HYGIENE, ANTIOCH COLLEGE, YELLOW SPRINGS, OHIO.

ANTIOCH College is undertaking to put into practice educational purposes and policies very generally approved in theory but seldom adopted in practice because of tremendous force of habit of doing things as they have been done. The Antioch program is an endeavor to prepare the students to meet the most universal and important experiences and issues in life; to give them the kind of knowledge most necessary to effective living in our present complicated economic system, and upon which they may wisely base important decisions materially affecting their well-being for all time. There is a blending of academic study with practical and the college program is so arranged that income earning experience may be gained where feasible in the calling for which the student is preparing himself.

While there is provision for full-time students, about 85 per cent of the student body divide their time between academic work at college and economic work outside. A single job is held by two students, who alternate in five-week shifts. The college work is divided about equally between technical and professional education and the essentials of a liberal education. In the liberal courses the student is given an acquaintance with fundamentals of nearly all the main fields of human knowledge and interest, rather than a more detailed knowledge of a few subjects. The technical or professional courses aim to prepare the student for responsible man-

agement and proprietorship in preference to making him a technical specialist working under orders. This training for proprietorship also aims to prepare for management in one of several specific callings, including educational administration, industrial organization, machine shop operation, printing and publishing, contracting, civil and mechanical engineering, manufacturing, merchandising, and institutional and household management. Four degrees are offered: Bachelor of Arts, Bachelor of Science, Master of Arts, and Master of Science.

The chief reason for the part-time work is its educational value. The ability of a student to support himself is the best possible training in self-reliance. Academic study supplies only a part of the factors of education. The student does not master his calling until he has practiced it; he does not know of what stuff he is made until he has tried himself out. If his work in industry gives meaning to his studies and his studies to his work, his development will be better balanced, and his apprenticeship after he leaves college will be shortened.

In the endeavor to determine the relative importance of human needs, problems and experiences, for which preparation should be made, certain well defined issues present themselves and in giving recognition to these issues it is found they, to a considerable extent, determine the content of the college program. Recognition is given to the physical well being of the students. It is considered a fundamental necessity for successful living. So at Antioch college, the development and maintenance of health and physical vigor are considered essential and are provided for in the curriculum. Since a human being must maintain good health in order to be most effective, physical education is required of every student. To know how to sleep, to eat, to exercise, to maintain correct posture, to resist disease, is fundamental.

Each student takes part in competitive athletics for the educational as well as the physical results. Intercollegiate athletics are encouraged within reasonable limits, but do not

dominate the college. This season, football, baseball, and basketball games have been played with other college teams, and similar schedules are arranged for the coming season. The girls are represented in basketball, tennis and hockey. As many students as possible represent the college in intercollegiate games. The others belong to intramural leagues in basketball, baseball, tennis, and track. The student is given wide freedom of choice in the required physical exercise, except where specific training is prescribed to remedy definite defects. Physical efficiency tests are given twice a year to measure the students' progress in physical development. The equipment for the department of physical education consists of a large gymnasium with basketball, volleyball, and indoor baseball courts and on the

Posture of students is classified using the Harvard scale. Most of Antioch's unselected students fall in Class B.

Actual drawings of Antioch students before and after corrective gymnastics.

campus a football and baseball field, tennis courts, and a limited amount of track and field equipment.

Each student receives a thorough and complete physical examination each year. If defects are found they are either corrected or the student is advised as to what he may do to overcome or remedy such defects. It is at times necessary for a student to consult a specialist for the purpose of completely removing certain defects. In the nearby cities of Xenia, Springfield, and Dayton there are oculists, aurists, surgeons, roentgenologists, dentists, and other specialists who co-operate with our medical department in looking after the physical needs of the students.

The students as a general rule do not object to physical examinations. On the other hand they seek them. Students show a growing interest in their physical welfare and are anxious to cooperate in the correction of defects found. When told that their physical condition is good they are greatly pleased and if any apprehension previously existed they are relieved of a burdensome anxiety. During the physical examinations the students are alone with the medical examiner for a time and most of them readily ask questions relating to their physical welfare, existing defects, and personal hygiene. This is one of the most important phases of the work.

Medical Supervision

The physical examination is thorough and includes all the important systems of the body. It embraces a full medical history of the student, together with a study of the heart, lungs, genito-urinary system, vision, hearing, teeth, throat including tonsils, the thyroid gland, the skin, the feet, posture, blood pressure, urinalysis, hemoglobin estimation, and the determination of the status of color vision. An outline drawing is made of the body side view for the purpose of making a posture rating and to file for future use in deciding whether improvement in posture has been made.

Special attention is given to posture and body mechanics. It has been found that good posture and efficiency go hand in hand. Students are rated according to their posture. If the body mechanics are found defective the student is assigned to a class in corrective exercises, conducted by the director of physical education. The student is then taught correct posture; the correction is fixed by physical exercises; then general exercises and sports in the fixed correct posture are

In order to insure a well-rounded diet, the dining room management spends as much for milk and fresh foods as for meat.

carried on in order to bring about a firm fixation of the correct-posture habit.

For the purpose of rating each student the four classes as evolved at Harvard university are followed. Class A shows good mechanical use of the body. The head is straight above the chest, hips and feet. The chest is up and forward. The abdomen is in or flat and the back curves are not exaggerated. Class B is not as good as class A but it is about as near the ideal as we generally find among unselected students. Compared with class A the head is more forward, and the chest not so well up. The abdomen and back are about as in the better class. Class C shows poor mechanical use. The head is forward, the chest flat, the abdomen relaxed and the back curves are exaggerated. Class D may be considered very poor as will be seen in the accompanying illustration.

Students who are rated as C or D are placed in corrective exercise classes which meet regularly in the gymnasium, and are given instruction and exercises which tend to develop good habits of posture. When good habits have been established corrective class-work ceases. In the last semester posture drawings are again made for comparison with those prepared earlier in the year. Two sets of drawings are herewith illustrated to show the same three students before and after corrective work.

As practically our whole student body spends half of its time away from the campus, in towns and cities, the risk of contracting certain diseases is greater. To meet these conditions all students are urged to take the anti-typhoid inoculations, vaccination against smallpox, and inocula-

tions of diphtheria toxin-antitoxin mixture. These are given without charge by the department. The number of students who have availed themselves of these opportunities is large. Antioch college, being situated in an endemic goiter belt, we are solicitous about the prevention and cure of this condition. All students found with simple enlarged thyroids are placed on iodine. As a prophylactic measure the whole student body is given minute doses of iodine by adding to one food of each meal the required amount of iodinated table salt.

Food Supervision

The drinking water and milk used at the college are under constant supervision and are daily examined in our departmental bacteriological laboratory. The sources of our food supplies, especially meats, are frequently inspected. All of our food handlers are repeatedly examined and also investigations are carried on to detect typhoid carriers among them. Practically all members of the student body eat at the college dining hall during residence. The foods are well selected as to quality and physiological balance. Some green or raw food is daily included in the menu.

The main purposes of our common college dining hall are convenience and accommodation of the students; the provision of good food and service at reasonable cost. At present, board is provided at the very low rate of four dollars and fifty cents per week, which makes the average per meal cost less than twenty-five cents. We attempt to feed not only scientifically but also acceptably. It is a pleasure to state that very little fault has been found on the part of the student

Women's dormitory showing entrance to dining hall where all the students eat.

body either with the quantity or the quality of the food, or the service. Three meals are served daily. Breakfast and luncheon are provided on the self-service cafeteria plan while evening dinner is served in family style. All of the dining room help is derived from the student body. The dining room is largely under student government control, criticisms and suggestions are invited, and a monthly financial statement of the refectory is posted.

As to the general character and variety of the food, it may be stated that meat is served at two meals daily with the exception that we have three meatless luncheons each week, at which meals some other nitrogenous food is substituted. Milk is liberally supplied. Coffee or cocoa is served with breakfast. Raw food of some kind is daily provided. In season, oranges, grapefruit, figs, dates, and fresh vegetables of various sorts are found on the tables. Five days a week salads of lettuce, cabbage or celery, and once a week spinach, are furnished. It is our aim to spend as much for milk and for fresh foods as for meats. At breakfast both cooked and uncooked cereals are at hand. A vegetable oil preparation, the purity of which is more fixed than that of butter derived from various and unknown sources, is substituted for butter.

The dietitians in charge of our kitchen and dining hall are also instructors in the college. Courses are given in nutrition and cookery for the purpose of giving young women basic knowledge of the nutritive value of foods. The choice, preparation, and

serving of the most common types of food are studied. Especial attention is given to manipulation and standardized products in cookery. Our kitchen and dining hall are used by selected students as a place for the practical application of theories evolved in the course in nutrition and cookery.

Antioch will not have put forth its greatest effort nor have accomplished its full purpose if it sends out into the world and industries men and women who are not physically fit. It is Antioch's object to have every student leave Antioch in better physical condition than he or she entered. If this ambition is not realized then the Antioch program will at least have failed in part. The effort to keep a true perspective of values and to bring about symmetry of development is fundamental at Antioch.

Results of the Recent Population Census

The final results of the fourteenth census summarized by Joseph A. Hill in the *Journal of the American Statistical Association* show a retardation of population growth. The increase in the percentage of urban population is more striking, all things considered, than in the previous decade, and results to a greater extent from cityward immigration. A decrease is shown in the percentage of the foreign-born—caused by the check to foreign immigration—and in the percentage of negroes, this last indicating a declining birth rate for that race. A decrease is noted in the proportion of children and adults under

thirty-five to the total population and a corresponding increase in the proportion over thirty-five. That during the past ten year the urban population has grown at the expense of the rural population is very apparent and, in view of the check in immigrant movement, the growth of cities has been largely domestic immigration. This domestic cityward immigration Hill estimates as between 3,000,000 and 4,000,000. He does not deplore the condition, but regards it as inevitable in a settled and growing country.

The percentages of foreign population he regards as misleading for the reason that children born of foreign parents the census classifies as natives. A more significant feature is the percentage of foreigners in the adult male population over 21 years of age. This percentage for the whole population is 22.1, more than 1/15 of the total. In the several states higher rates are given as 35.4 for the middle Atlantic states (New York, New Jersey, and Pennsylvania) 38.2 in the New England states; in Massachusetts and Boston 46 per cent; and in New York City 53.4 per cent.

The decrease in the proportion of children probably reflects a declining birth rate. This effect is partially disguised by the diminishing infant mortality rate. Some influence in percentages is likewise registered in a diminishing death rate in the period of middle age. The change in age composition is not a new trend but is more noticeable than in the census of 1910.

Mental Hygiene in Arizona

Several points of interest stand out from the published report of Thomas H. Haines in *Southwest Medicine* of the results of the mental hygiene survey of Arizona just completed with the cooperation of the National Committee for Mental Hygiene: (1) the percentage of psychopaths, neuropaths, and epileptics is low; (2) the retardation among Indian school children is relatively high; (3) that figures of normals and defectives in the reformatories appear more favorable than in the Indian group.

A fund of \$60,000 has been left under the will of the late William G. Vincent to establish a chair of tropical disease at Tulane University of Louisiana School of Medicine, New Orleans. Thirty thousand dollars has also been set aside for the erection of an isolation building for the Charity Hospital, New Orleans.

Reconstruct Old Physic Garden in St. Louis

The old Chelsea Physic Garden in London, which is still in existence and which was visited by Linnaeus in 1732, has been reproduced in St. Louis. It is described in the *Journal of the American Medical Association*.

While synthetic medicaments have held the focus of medical attention during the last two decades, those which may be obtained from medicinal plants have continued to be of great utility, and many even irreplaceable. Such plant derivatives as cinchona, aconite, opium, rhubarb and senna still command a wide range of use in medical practice. For this reason the exhibit at St. Louis by the Missouri Botanical Gardens of a reproduction of the old Chelsea Physic Garden attracted a large number of the physicians who visited the annual session of the association.

A recent issue of the bulletin published by this organization is devoted to an historical discussion of the famous garden which was reproduced. Even in 1673, as shown by this report, it was necessary to protect the physician and dealer in drugs against unsatisfactory and inefficacious counterfeits of valuable drug substances, and this necessity led to the establishment of the Chelsea garden.

A greenhouse, heated by so-called "subterranean heat" conveyed by means of a brick flue under the conservatory, was erected in 1681, and in 1732 the garden was visited by Linnaeus, who states in his diary that he collected many plants in the garden and that he was given several dried specimens from South America. The Chelsea garden is still maintained, although now administered by the trustees of the London Parochial Charities.

In the exhibit as made in St. Louis, the reproduction followed is the plan of the Chelsea garden drawn by John Hayes in 1753. To complete this demonstration the authorities of the Missouri Botanical Garden gathered in the museum building copies of old works on materia medica and other incunabula on botanic subjects of medical interest, and also provided demonstrations on the diseases of plants. The medical profession is greatly indebted to authorities of the Missouri institution for this practical historical demonstration of botanic therapy.

The Minnesota Commission for the Blind appointed by the governor in a report now in the legislature recommends that special funds be given the state board of health to maintain trachoma clinics. Surgeon Taliaferro Clark, U. S. Public Health Service, and Dr. L. L. Culp, Bureau of Indian Affairs, in December, 1922, examined 13,919 persons, chiefly school children, finding 77 cases of trachoma and 24 suspicious cases. Examinations were conducted in 108 schools in 70 sanitary districts of 13 counties.

Illinois is now in the U. S. birth registration area. An intensive birth registration campaign carried on for eighteen months by Isaac D. Rawlings, state health commissioner, resulted in the 90 per cent registration necessary.

Industrial Welfare Society, 51 Palace street, Westminster, London, S. W. 1, is preparing a brochure on pensions and superannuation schemes which will be sent to members or readers of *Industrial Welfare* on request.

A Protest From Iowa

By T. J. EDMONDS, EXECUTIVE SECRETARY, IOWA TUBERCULOSIS ASSOCIATION
DES MOINES, IOWA.

IN AN otherwise very excellent article in *The Nation's Health* for December, Dr. E. H. Lewinski-Corwin states that the standing committee of the New York Academy of Medicine "under its present organization is the only organization of its kind in the world." He further says that "none of the medical bodies abroad or in this country maintain a sustained interest in current public health problems as they arise, or consider them from the broad view of municipal policy and in the light of accumulated thought and knowledge which comes from a continuous contact with the whole realm of public health." A writer always incurs a risk in using either superlatives or terms of exclusion. Frequently an initially correct assertion ceases to be true before it emerges into print. Admonished by the experience of Dr. Corwin I shall not claim that the Field Activities Committee of the Iowa State Medical Society is the only year-round operative department of a state medical society with a paid director established for the purpose of activating the medical profession in relation to public health work, for sustained cooperation with lay social and health agencies, and for definite planning and functioning in public health endeavors on the part of both county and state medical societies. At least, however, this development of the Iowa Society is unique and is being watched with interest by other state societies and by the American Medical Association, and various national organizations.

The personnel of the Field Activities Committee is in itself indicative of cooperation in public health work. The director, Dr. F. E. Sampson, is the founder of the Community Hospital, located at Creston, serving a group of counties; he is a prolific writer on popular as well as technical medical subjects; he is now serving his second term as president of the State Conference of Social Work. The committee members are: Doctors F. E. Samp-

son, director; O. J. Fay, president-elect; W. L. Biering of Des Moines and B. L. Eiker of Leon, representing the Council of the State Medical Society; Dr. N. G. Alcock, representing the University of Iowa Medical faculty; Dr. R. P. Fagan, representing the State Board of Health; Dr. James Edwards of the Iowa State College, representing the State Conference of Social Work; T. J. Edmonds, representing the Iowa Tuberculosis Association. Dr. Biering is chairman and Mr. Edmonds secretary of the committee.

In the four months during which Dr. Sampson and the committee have been functioning the director has addressed meetings in fifty-one localities, has conferred locally with thirty-nine county medical societies, has secured the publication of five magazine and 150 newspaper articles relating to the work. One of the latter was a double column first page article in the Sunday edition of the largest newspaper in the state—a perfectly legitimate means of advertising which was worth hundreds of dollars to the profession. He has motivated county medical societies in at least twenty counties in the state to active cooperation with lay public health movements—especially in support of the Christmas seal sale of the Tuberculosis Association. The good will accruing to the profession through this pledge of interest in preventive medicine and community health work has not done the practitioners any harm.

As this article goes to press there is in session a joint meeting of the committee and the councillors of the state medical society. Subjects under consideration are: The Inactive County Medical Society, County Public Health Associations, the Sheppard-Towner Administration, the Rockefeller Foundation gift to the medical department of the State University, Public Health Legislation, discussed by men from the University, the State Board of Health, the Rockefeller Foundation and lay organizations.

Iowa Develops Unique Plan for Hospital Service

Medical Care Is to Be Equitably Distributed According to Need

By F. E. SAMPSON, M. D., DIRECTOR OF FIELD ACTIVITIES OF THE IOWA STATE MEDICAL SOCIETY, CRESTON, IA.

IN RECOGNITION of the need for correcting the increasing tendency toward congestion of the large cities, and its corresponding depletion of the less densely populated localities as regards resident medical practitioners, the Iowa State Medical Society at its annual meeting in May, 1921, delegated to a special committee the duty of formulating a plan for the correction of such disorder.

From the resolutions which were adopted by the House of Delegates defining the objects of the proposed plan, it was evident that the Iowa State Medical Society proposed to "hatch out," and become a continuously functioning institution instead of limiting its activities to those of a scientific society holding annual debates and expecting a few standing committees to meet all such grave emergencies that arise between annual sessions as invasion of the realm of science by predatory cults and ignorant pretenders seeking legislative privilege.

The specifications for the plan provide for medical field activities to be carried on under the guidance of a full time director, that effort to be devoted (1) to perfecting organization and encouraging sustained activity of the ninety-nine component county medical societies; (2) stimulating interest and activity of such societies along public health lines; and to effecting co-operation between such societies and other agencies of the community as are engaged in related activities.

Without enumeration of all the specifications, it is sufficient for present purposes to state that the ultimate purpose is to promote efficient and equitably distributed medical service throughout the state of Iowa.

Such a plan must inevitably accord a large share of consideration to hos-

pitals not only to encourage the building of hospitals where needed, but also to promote high standards of service.

Of interest in this connection is the fact that Iowa has what is known as the enabling County Public Hospital Law under the provisions of which the people of any county may vote bonds to build and equip, and levy a tax to maintain a hospital. Such

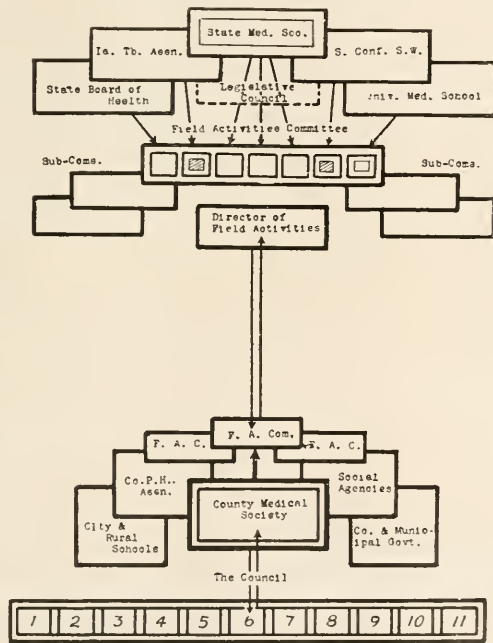

cal practitioners do not attract the recent graduate, it is not far to seek. The community that expects a doctor to come, or remain if chance brings him among them, and deliver a full measure of modern medical service with the same limited facilities that sufficed for dear old doctor Saddlebags might as well expect to fill the vacancy of lamented old dobbie and make the ancient buggy "go" by pouring gasoline in the whip-socket.

Ignoring, for the present, the modern tendency to specialize immediately on completion of the internship, the young man seeking a location for general practice of medicine must have the qualities of the pioneer or be strongly charged with the missionary spirit that forgets self in the glory of service for dear humanity's sake, if he can see opportunity for worthwhile investment of himself where even the beginnings for a modern hospital are not within working range.

But building hospitals by no means solves the problem. Indispensable as they are to the solution, the building and maintenance of hospitals in localities that need them is but one of the many factors essential to making medical service fully efficient throughout the state of Iowa. Buying a perfectly good piano does not assure high class music. (This simile is limited if not lame, because nothing like the mechanical player attachment for the

piano has yet been devised that will make a hospital function efficiently.) Our state is not without localities in which the premature construction of a perfectly good hospital building, fully equipped and moderately endowed, has actually complicated the problem as concerns the development of truly efficient service.

Even when a hospital is obtained

Organization chart, showing interdependence of all health, medical, and social organizations in the state. Each functions in and through the other in field service both as a stimulus and a check on the other, evidencing a real talent for organization. Upper portions of diagram show the social forces from which the Field Activities Committee derives its members. Lower portion indicates the general plan of coordination.

power under the law, however, has not as yet shown any remarkable solution for the problem of inadequate and inequitably distributed hospitals. Only five such hospitals are in operation. In a dozen other counties, the proposition has been submitted only to meet overwhelming defeat.

Why localities in greatest need of the services of capable resident medi-

under provisions of our enabling hospital law, a very considerable margin of uncertainty will remain until such time as minimum standards of service are demanded for all hospitals, and the slogan used in some of the hospital campaigns—"equality of privilege" for all doctors, is relegated in favor of "*equality of opportunity for all who will conform to modern standard regulations.*"

Assembling the conclusions drawn from study of the many involved factors, the situation was found to be this:

(1) The smaller cities and rural communities of Iowa can not attract and keep the kind of medical practitioners they need unless something approximating modern hospital facilities is provided.

(2) The people of such communities, though they do contribute as church members to the maintenance of denominational hospitals elsewhere, will not tax themselves or otherwise contribute to the building and support of a hospital in their own community until shown that a hospital means more than an operating room surrounded by rooms for the convalescence of those who survive the operations.

It is one of those frequent occurrences in human affairs involving community of endeavor in which the driving wheels get caught on center—a sort of vicious circle—that we sometimes try to correct by prescribing for symptoms instead of tracing back to causes before we decide on the treatment. This vicious circle some would break with the hammer of mandatory legislation and pay for immediate relief in reactionary complications, perhaps *calamitous* in nature.

A committee on field activities is made a standing committee of the State Medical Society. Its duties include those formerly delegated to the Committee on Health and Public Instruction.

It shall be the function of this Committee to collaborate with the Council as a body and with its members in the formulation and carrying out of programs in their respective districts. It shall be the special agency through which the State Medical Society and other agencies concerned with related activities may establish sustained working relations, formulate joint programs, and promote interest and activity in lines calculated to increase the adequacy, efficiency, and equality of distribution of applied medical science throughout the State of Iowa.

The number of members shall be seven. With the exception of two below mentioned, the members of this Committee shall be members in good standing in the Iowa State Medical Society.

The president-elect shall be an ex-officio member of this committee from his election until his inauguration as president. The other six members shall be selected as follows:

Two shall be nominated and elected by the Council. The other four to be apportioned and selected as follows:

One is to be chosen by the Iowa State Board of Health.

One by the faculty of the University of Iowa Medical School. (Both these to be members in good standing of the Iowa State Medical Society.)

One to be chosen by the Executive Committee of the Iowa Tuberculosis Association.

One by the Executive Committee of the Iowa State Conference of Social Work. (The last two named may be chosen by their respective organizations for their fitness to represent the specifically declared purposes of the organization.)

Except the president-elect, the members of this committee shall be elected for two years. (Those elected by the Council are to cast lots for the short term so that one of the two will be elected at each annual meeting after 1922.)

The Committee on Field Activities shall be empowered to employ such help as it deems necessary within the limit of the aggregate appropriation approved by the Board of Trustees and House of Delegates of the state society; to enter into such working agreements with associated agencies as it may deem wise and proper; to recruit volunteer speakers' bureau and to pay the actual expenses of such speakers; and to defray also the actual expenses of members of the committee that are incurred in performance of duties connected therewith subject to the same rules and restrictions that apply to the Board of Trustees. All bills for expenditure of the appropriation shall be subject to approval of the Board of Trustees of the Iowa State Medical Society after which, warrants for payment of same shall be made according to the provisions of the Iowa State Medical Society's by-laws. The committee shall not incur obligations beyond the provisions of the appropriations placed at its disposal by the House of Delegates, but this shall not prohibit expenditure of funds that may be derived otherwise than through said appropriations.

The plan recognizes the county medical societies as the terminal functioning units of the State Medical Society, as aggregations of local practitioners of medicine functioning as a local influence in local affairs and collaborating with other local forces in definite local programs that aim to solve problems of importance to people of the local community, as well as to the local practitioners. This is in contrast with policies thus far followed by most of our state medical societies in which the central organization distributed its service to the members as individuals, and, aside from collecting annual dues of such members, neither demanded of, nor delivered to the county society much, if anything, more than recognition as a register of local members of the State Society.

The object of the proposed field activities is to develop our county societies as responsive and responsible medical aggregations, that shall sustainably function in their respective counties, not only within themselves as scientific bodies, but in cooperation with other agencies concerned with conserving the health of the community.

Women Voters Will Push Social Hygiene Bill

The winter's federal legislative program of the National League of Women Voters has as its right-of-way measure to which all other measures must give place House and Senate bill (H.R. 11490 and S. 3544) which provides for the carrying on by the Department of Justice of the work of the Interdepartmental Social Hygiene Board. Mrs. Ann Webster, chairman of the League's national committee on social hygiene and chairman of the sub-committee of the Women's Joint Congressional Committee will, according to *The Social Hygiene Bulletin*, direct this work as well as urging on state League committees the necessity of working in thirty-four states for the enactment of the standard vice-repressive law which in defining ing prostitution as an offense of both sexes enables the authorities to hold the man as well as the woman.

The Public Recreation Committee of the Brooklyn Chamber of Commerce is making a survey of the Borough to determine where parks and playgrounds should be placed. It is urging that the city establish a few large parks and a large number of small ones, especially in territory not yet built up where land is still cheap.

School Lighting to Conserve Vision

By A. L. POWELL AND A. D. BELL, LIGHTING SERVICE DEPARTMENT, EDISON LAMP WORKS, GENERAL ELECTRIC COMPANY, HARRISON, N. J.

AN EDUCATIONAL system which permits from eight to fifteen per cent of its children to acquire defective vision within the few years of their school lives has something intrinsically wrong. The fact that eye troubles are more prevalent among children in the advanced grades indicates that this strain is increasing. In most cases, the child receives his first exacting eye work when he goes to school where from necessity a large quantity of printed and written matter is placed before him.

It can, therefore, be easily understood how a child, born with normal vision but forced to do detailed work, oftentimes under inadequate illumination develops poor eyesight. It is essential, therefore, to provide good illumination in the school that those pupils with normal eyes may see properly and that those with defective vision may do better work. Backwardness of many pupils, formerly ascribed to mental deficiency, has been caused by defective vision. In this connection alone, proper lighting of the schoolroom is an economy as the cost of teaching the pupil forced to spend an extra year in school because of defective vision offsets any saving in lighting expenditure.

In the majority of schools, arrangements for daylight are satisfactory but artificial lighting is frequently inadequate. Systems in use often consist of bare, clear incandescent lamps, and where reflectors are used, units

are frequently hung in such positions as to produce eyestrain. Again, intensity of illumination is often far too low.

Artificial lighting is necessary in schools to supplement daylight on cloudy and stormy days. The crowding of schools in the last few years has made night sessions a common practice which calls for good illumination if the student's vision is to be conserved.

With the unit of intensity of illumination the foot-candle, defined as the illumination on a surface normal to a one-candle-power source at a distance of one foot, the following table of light has been worked out for the school:

Classroom	5-7 foot-candles on desks
Study room	6-10 foot-candles on desks
Office	6-8 foot-candles on desks
Cloak room	3 foot-candles on floor
Corridor	1-2 foot-candles on floor
Laboratory	8-10 foot-candles on tables
Auditorium	3-6 foot-candles on floor
Drawing	8-12 foot-candles on tables

A distinction must be drawn between those classrooms which are used for clerical work, reading, and writing, and those used for sewing, art, metal work, drafting, chemical experiments, and the like. The latter rooms should be illuminated to the higher values given in the tables. Fine needle work by young children should be done only in daylight.

Elimination of glare in school lighting is most important as it is this factor which causes the greatest amount of eyestrain. When bright light sources are placed high above

the head as the noonday sun, the eyebrows protect the eyes, but indoors lights often must be hung low, thereby coming within the field of vision. This brilliancy can be reduced by diffusing globes, shades, or reflectors which either effectively enlarge the light sources or actually hide them from view. Care should be taken, however, that over-diffusion or flat illumination does not occur as this condition is trying to the eyes.

Not only must light sources be considered in providing diffusion, but the walls and other objects must be given attention. Dull rather than polished surfaces are desirable, and even a polished or waxed finish is more desirable than varnished or highly polished surfaces on the desk and other furniture, as the latter produce mirrorlike effects in reflecting the light sources. In this connection, attention should also be given to the desirability of mat rather than glossy finished paper, for paper with a glossy finish likewise reflects light in an annoying manner.

Distribution of light has two extremes—local lighting and general illumination. In local lighting relatively low candle-power light sources, located rather close to the work, furnish a high intensity of illumination over a small area. There is a tendency to use local lighting in drafting rooms, machine shops, and sewing rooms. The lamp is often under the control of the pupil who knows little of its proper use and often works in

Classroom in Public School 21, New York City, showing how light tinted walls and ceiling aid illumination. The semi-indirect unit system gives excellent diffusion and eliminates direct and reflected glare.

General lighting with fixtures above the students' vision has been found more effective in laboratories than individual lights subject to control of the pupil.

Tinting of walls and ceiling of this high school classroom would greatly increase illumination.

Overhead illumination simulating daylight is the system best suited for schoolroom lighting.

his shadow. Local lights often cause annoying glare to pupils at adjacent tables and drop cords are often tied back which constitutes a dangerous practice.

In general illumination, much larger lamps, hung as high as possible and providing almost uniform lighting throughout the room, are used. This system simulates daylight and is best suited for schoolroom lighting. It has the advantage of a less expensive wiring, less danger from breakage of lamps, and produces less glare. No lighting unit should be hung below a line extended from the eye of a student in the rear seat to a point two feet above the blackboard.

Eliminating glare from blackboards will also aid in conserving the eyes of the pupil. To minimize glare, blackboards should have matt rather than polished surfaces. They should never be located between windows.

Direct, semi-direct, and totally indirect systems are all employed in school lighting. Totally indirect lighting produces a very high quality of illumination but requires a relatively large wattage for a given intensity. With such a system, there is little possibility of glare and the light is soft and comfortable to work under. The inverted bowls, however, tend to accumulate dirt and unless cleaned frequently the light output is materially reduced.

Semi-indirect lighting is an intermediate practice, most of the light from the lamps being directed to the ceiling with a slight amount transmitted through the glassware. It is slightly more efficient than totally indirect lighting; the resultant illumination is well diffused; and such shadows as are produced are soft and cause no annoyance. The best forms

of semi-indirect units for school work employ dense glass or some other means of reducing brightness of the lighting unit.

In many of the older installations, open bottom, direct lighting units are used. Such a system is obviously efficient from the standpoint of light utilization, but the diffusion is not of the highest quality, shadows and contrasts are likely to be rather severe, and direct and reflected glare become serious, particularly if clear bulb lamps are employed. The use of this form of lighting is advisable only where costs must be kept at a minimum and where secondary consideration is given to the quality of illumination. Where direct lighting is deemed advisable, dense opal or etched prismatic reflectors should be used. These transmit but a small portion of the light, and are, therefore, not very bright. The flat type reflectors should never be used in a schoolroom, for it is almost impossible to conceal the filament from view when using this style of shade. Opaque reflectors are, of course, generally unsuited, as the ceiling would be very dark when these are used.

In view of the above analysis, the enclosing, diffusing, direct lighting luminaire seems to be, at the present state of the art, the most generally applicable equipment for classroom lighting. If the proper type is chosen, a well diffused illumination quite free from direct or reflected glare is produced. Although the major portion of the light is directed downward, a considerable amount is transmitted upward, thus giving a cheerful appearance to the room and a character of illumination closely akin to that produced by semi-indirect units. Such equipment does not depreciate as rap-

idly with accumulation of dirt as do other fixtures producing the same general quality of illumination, but cleaning should not be neglected.

Light colored walls and ceilings always aid in any system of illumination. Light on the ceiling is very desirable for when reflected downward it reduces contrasts and softens shadows. Therefore it is generally advisable to paint ceilings light tints regardless of type of lighting installed. Deep crevices in glass, though decorative, accumulate dust.

Part of the equipment of any school system interested in conserving vision is the small portable photometer known as the foot candle meter, which measures illumination on desk, workbench, or table.

Adequate illumination in schools is vital to the health of the school child and will be a great step in preventing visual defect.

Health teaching was given an important place on the program of the Pennsylvania State Education Association, which met at Bethlehem in January. Dr. Thomas D. Wood, professor of physical education, Columbia University, stated that health education should be closely correlated with other school subjects. Dr. Charles H. Keene and Miss Anna L. Stanley, state department of public education, also urged that health be made an integral part of every school program.

Seventy-five per cent of initial decay resulting in ultimate loss of molars begins on the grinding surface of teeth, says Dr. Thaddeus P. Hyatt, dental director, Metropolitan Life Insurance Company.

Health Equipment in Framingham—Then and Now

**Tuberculosis Decreases 55 Per Cent
And General Death Rate 16 Per Cent**

By DONALD B. ARMSTRONG, M.D., EXECUTIVE OFFICER, AND A. K. STONE, M.D., ADMINISTRATIVE DIRECTOR,
FRAMINGHAM, MASS.

THE Community Health and Tuberculosis Demonstration was started in Framingham January 1, 1917, by the National Tuberculosis Association with the financial assistance of the Metropolitan Life Insurance Company to determine whether it was possible to diminish both morbidity and mortality from tuberculosis in a community with an average equipment for health work. Under the guidance of a national committee appointed by the national association, an attempt was made to discover the amount of tuberculosis, active or latent, in a population of seventeen thousand people, and to try to bring the disease under observation and control. It was further hoped that the amount of fresh tuberculosis developing in Framingham could be diminished and consequently the volume of future devastating sickness and death permanently reduced.

The changes that have come in the machinery for combating tuberculosis in Framingham in the six years of the demonstration, as a result of local efforts to accomplish these ends, are interesting from several points of view. First, they reflect what was considered fairly good work six years ago. Second, they suggest what may be considered relatively advanced health equipment at the present time, operated under fully responsible local auspices, and largely financed from town funds, either public or private.

Framingham's greatest practical advances have been in improvement in municipal methods of attack on tuberculosis by the board of health and school committee and in popularization of health knowledge among the townspeople. This latter has developed in part from medical supervision of so many people in the community by private physicians, medical staffs of the larger manufacturing plants, insurance companies, and finally through educational work of the demonstration itself.

So successful has been the work of the demonstration that almost the entire community program has been locally assumed, and it is looking forward to the time when it can advisedly withdraw from direct local participation.

Framingham's greatest practical advances have been, first, in the improvement in the municipal methods of attack on tuberculosis by the board of health and school committee; and second, in the great popularization of health knowledge among the townspeople. This latter has developed in part from the medical supervision of so many people in the community by

private physicians, by medical staffs of the larger manufacturing plants, by insurance companies who supervise health of their policy holders and families, and finally through educational work of the demonstration itself.

Changes which have taken place in Framingham are summarized briefly below. The community machinery, still incomplete in many respects, represents a development based upon a growing conception on the part of the town itself and its leaders in politics and industry as to what constitutes adequate health work.

In 1916 the board of health had recently appointed a full-time health officer who had under his supervision the following activities: Laboratory examinations, quarantine of contagious cases and care of tuberculosis cases, and certain police duties imposed upon the board by the laws of the commonwealth. There was a small though fairly complete laboratory equipment. The cost of health work for this year was \$8,061.79. A tuberculosis clinic had been carried on by the local tuberculosis association, but was taken over by the board of health the latter part of 1916.

In 1921, in addition to the above mentioned activities, the following services were added under the direction of the health officer: One tuberculosis nurse (an active visiting list of approximately 100 names); one

tuberculosis clinic with consultant on call at all times; two infant and preschool nurses (450 babies visited regularly); three part-time infant welfare physicians; four infant clinics in various sections of the town; one infantile paralysis clinic—semi-monthly; one venereal disease clinic—weekly.

The department has recently moved its quarters to the building in which are located the other town offices and has fitted up its rooms at a cost of \$1,400. The new laboratory is well arranged and equipped with ample space for all services. The health work as carried out by the board of health in 1921 cost \$18,607.04, an increase of 130 per cent over 1916. The 1922 budget as requested and granted totaled \$20,000.

In 1916 there were in the Framingham schools 3,039 children. At this time the health machinery consisted of a part-time physician and one full-time nurse. Physical examinations were made on the request of nurse or teacher. The amount expended in 1916 for health was \$1,518.50.

In 1921, with a school population of 3,349, the health work as carried on was as follows: One physician with full interest, but devoting half-time to school work. This is not enough time to allow for proper study of over 3,000 school children; one nurse (assists physician with examinations, visits absentees reported ill, etc.); one dental hygienist (cleans mouths, gives talks to classes, holds tooth brush drills, etc.); one dental clinic with complete outfit; two dentists in charge one day each week (number of fillings in 1921, 706, in addition to other treatments); one gymnastic director and physical educator, and instructor in physical training. The above health work cost approximately \$5,976.10 in 1921, an increase of nearly 300 per cent over 1916.

Under the joint auspices of the school committee and board of health, 900 children have been given the Schick test.

In 1916 there were two modern school buildings in Framingham and the survey, reported in Monograph No. 6, repeatedly mentions the need for new buildings. Two of these have been completed and are of the most satisfactory modern equipment.

Appropriations have been made for two additional buildings and one of these is well along in its construction. The site for the fourth has been selected and the plans approved. The total cost of the four new buildings will be approximately \$790,000.

The machinery for improving health

and preventing accidents in industry has steadily increased due in part to the general laws of the state. Advances made in two of the largest industries in the community are as follows:

(A) *Largest Industry*.—In 1916 2,200 were employed. The health work consisted of one nurse, rest room, one-room clinic, physician on call, or two visits a week, a sick benefit association for male and female employees. The cost for this service amounted to \$2,842.

In 1921 there were 2,700 people employed. Health equipment was as follows:

One full-time physician; two nurses; one rest room; three-room clinic; surgical, throat, dental, and ophthalmological outfits; sick benefit associations now assure three weeks hospital treatment, if necessary, in any year to all members. Membership is \$2.00 a year.

Industrial Health

Further developments in this industry have been the examination of all new employees by the plant physician, this procedure being at the request of the works committee. Special medical supervision of department heads is carried out by a local physician, and the services of the Health Demonstration consultant are called for on questionable tuberculosis cases. The cost of the health work for 1921 was \$9,412. In July 1922 an up-to-date dental clinic was installed with a full-time dentist in charge. Although the expenditure is large the administration feels that increased efficiency of the employees amply justifies the outlay.

One of the worst of the tenement blocks in the town is soon to be purchased by this industry. It will probably be demolished as soon as the erection of new houses justifies the action. This will mean a great advance in the sanitation of living conditions.

(B) *Next Largest Industry*.—In 1916 this concern had no health work. In 1921 under new management and employing 670 people the equipment for health conservation was as follows: One full-time nurse with clinic and small rest room; minor surgical outfit; compulsory examinations for all new employees; services of health station consultant for the carrying on of voluntary medical examinations for old staff, and examinations of all new employees. Six hundred and fifty examinations were given from September, 1921 to September, 1922.

This concern has made some improvements in their tenement property and a betterment of sanitary conditions will doubtless be effected when a new sewer system, now under way, is completed.

Correlative Agencies

(a) *Civic League*.—The Civic League was organized in 1917, the new building and swimming pool being opened to the public May 1, 1918. Infant welfare work was inaugurated and expanded by this private body, at first financed by the Community Health Demonstration and later taken over by the official health authorities. General health and educational work has been carried on regularly, gymnasium facilities are offered to the public and health clubs and community garden clubs formed. The estimated cost of the health aspects of the work is \$2,500.

(b) *Hospitals*.—There are two hospitals in the town, one of which containing one hundred beds, is partially endowed, and the other of thirty beds is privately conducted but open to the public. Both hospitals have training schools connected, the student nurses aiding in several important demonstration activities. One of the hospitals has a district nursing service connected with the training school. Both hospitals have first-class x-ray plants, the equipment in one of them being supplemented from demonstration funds. In 1922 a group of women citizens further contributed \$1,500 for increasing the x-ray facilities.

(c) *Park commission*.—This commission has cooperated by offering the facilities of the public parks and playgrounds where the children of Framingham benefit by healthful and supervised play. Five playgrounds in all, financed wholly by this commission, were operated in 1921. A physical director has supervision of the playgrounds, the cost of their operation in 1921 being approximately \$2,000. In addition, the park commission has loaned to the demonstration an old Fair Grounds building for children's camp purposes, throughout several summers.

(d) *Framingham Women's club*.—The "Mother Craft" idea was introduced into one of the schools at the instance of the Women's Club. This may be taken over eventually by the school department.

(e) *General Conditions*: (1) *Sewerage*.—In 1916 the town had a sewerage system only in the southerly section, as reported in the demonstra-

tion sanitary survey. A plan has been devised for a sewerage system for Saxonville and the Center Village but was held up until 1922 when a report of a new committee was adopted and an appropriation of \$300,000 made to carry out the work. Surveys for this work are being carried on at present and contracts will be let early in 1923. This will fill a long recognized need in the sanitary conditions of the town.

(2) *Milk Consumption*—The main distributors of milk in Framingham state that there has been a marked increase in milk consumption during the demonstration period. Families who averaged one pint to one quart daily in 1916 are now using one quart and a half to two quarts daily. The percentage of pasteurized milk has increased from about 15 per cent to between 70 and 80 per cent.

The presence of the demonstration in Framingham has added materially to the ordinary health work being done, and the town must be considered exceptional on account of its stimulative influence. In addition to the assistance and stimulation given toward the development of practical, routine, and permanent health services, and in addition to general health educational work, the demonstration contacts with professional groups have been most helpful and significant.

One outstanding result of the work, not enumerated above, is the increased interest of the physicians in tuberculosis, and their keen desire to discover new and early cases. It was at the request of local physicians that the most important contribution of the demonstration to the early discovery of tuberculosis was developed. The demonstration was urged to provide a consultant to see certain cases of doubtful tuberculosis, the calls becoming so frequent that a permanent medical examiner, Dr. P. C. Bartlett, was added to the staff. These contacts with the local medical men have averaged about three hundred consultations each year, the service being utilized by practically all practising physicians in the town. This measure, unique in tuberculosis work, has greatly aided in the recognition of tuberculosis at an early stage.

The consultant has found it desirable not to confine his work to tuberculosis alone, but, so far as he was able, has given assistance in general medicine, with the result that by his constant contact with the physicians he has come to pass upon many cases where tuberculosis, while not originally suspected, was subsequently discovered. The physicians of the town have abundantly endorsed the prac-

tical value of this consultation service to them and to the whole community.

Results of some of the investigative activities undertaken by the demonstration may also be summarized as follows:

(1) The health census disclosed 6.2 per cent ill, 1.8 per cent strictly incapacitated, 6,582 people being enumerated.

(2) Examination of thousands of men, women, and children in Framingham showed that approximately 1 per cent were suffering from active tuberculosis, 1 per cent from arrested tuberculosis, and 77 per cent from all forms of illness and disability.

(3) Four hundred and sixty children, 1 to 7 years, had the von Pirquet test in 1917. The 33 per cent who reacted positively and who were subsequently followed at four different intervals disclosed no cases of recognizable tuberculosis.

(4) Seven hundred people who had influenza during the epidemic of 1918-1919 were physically examined three months after the onset. Active cases of tuberculosis were found in 2 per cent. There have been three subsequent follow-ups of this group, with largely negative results so far as tuberculosis was concerned.

(5) The intensive medical work of the demonstration, the school and factory examinations, as well as the work of the physicians during the first year of the demonstration brought to light 9 or 10 active tuberculosis cases for every annual tuberculosis death.

(6) Before the demonstration started in Framingham 45 per cent of the tuberculosis cases were reported in the early stage; now about 75 per cent of the cases are being reported as early-stage tuberculosis.

(7) The minimum tuberculosis hospital bed requirement in Framingham during the demonstration has been from one to two beds for every annual tuberculosis death in the community. An abstract from a letter dated September 27, 1921 from Dr. Roger I. Lee, chairman of the appraisal committee on treatment, follows:

Furthermore, since the town of Framingham has done better than to keep one tuberculosis patient in a sanatorium for each death from tuberculosis, it is evident that such a showing indicates a high standard of treatment. These figures are of course not even approached in the state of Massachusetts or in any city or town with which I am familiar.

(8) For five years the health sta-

tion has conducted a health camp for under-nourished children, approximately 350 children having had the benefits of such a camp.

(9) The amount of tuberculosis in the community, active and latent, has been disclosed with a degree of completeness perhaps never before achieved, while new cases developing are promptly recognized and put under observation and treatment. The amount of morbidity from tuberculosis among young people who have come into adult life under the health campaign of the past six years has very evidently diminished, all of which should reflect itself very favorably and permanently in the health and sickness records of the community in the coming years.

(10) The sixth year of the demonstration, 1922, the last for which complete records are now available showed a decline of 16 per cent in the general death rate under the pre-demonstration decade average 1907-16, an improvement of 25 per cent in the infant mortality rate as compared with 1916, and a reduction for 1921-22 combined of 55 per cent in the tuberculosis rate under 1907-16 when corrected from resident and certification errors.

This growth and development of the town's activities, involving an increase in expenditures for local practical health services from 40 cents to about \$2.25 per capita per year, while stimulated and in some instances subsidized at least temporarily by the demonstration, has been for the most part carried out under local leadership. This reflects the belief of the committee in charge of the demonstration, that there is both willingness and ability to develop and support an adequate health program.

The demonstration is looking forward to the time when it may advisably withdraw completely from direct local participation. It is still interested in the consultation service, in the further coordination of local services, in the enhancement of adequate, official, local health leadership, and in the statistical results of the work. Yet almost the entire community program has been locally assumed, results are promising, and the termination, other than minimum provision for continued observation, seems not far distant.

A new child welfare station was opened in Cuba in November under the direction of Dr. Fernando Llanos. On the opening day a large quantity of sterilized milk was distributed.

Boston Women Learn Sanitary Inspection

WOMEN are being taught municipal housekeeping in the School of Public Service, established by the Women's Municipal League of Boston and the Massachusetts Committee of the National Civic Federation. Inspection of street cleaning, markets, and tenements are

drainage, cleanliness of stairs, halls, cellars, and yards. Food inspectors learn construction, plumbing, ventilation, and cleanliness, and how to score restaurants, markets, provision stores, bakeries, and ice cream and candy factories. Street and alley inspectors learn standards of cleanliness, house

cient garbage collectors and with indifferent owners of stores and factories who block passageways with piles of refuse.

Student sanitary inspectors tour the rooming-house district, the foreign sections where sidewalks are cluttered with tubs swimming with grape skins and vermin, the manufacturing district where loosely piled refuse blocks the streets.

A typical report of such a walk made by a student of the school reads:

Alley at clean except entrance to street which is littered with refuse. Mostly all the receptacles here are wooden. Collections had been made but several barrels filled with rubbish and ashes remained. This needs to be followed up to ascertain who is responsible—city men in overlooking them or householder late in putting barrels out. Several barrels in bad shape, one in particular broken and ashes thrown out.

Alley at covered with cans and papers. Two large holes in alley dangerous for horse and wagon.

The courses for policewomen and school attendance officers are equally practical.

So many applicants for the school were received that a second class had to be formed later in the spring of 1922. The limit of eighteen to each class insures personal interviews and individual instruction which is calculated to overcome differences in education, equipment, and experience among the women.

Tours of inspection to foreign districts where junk piled streets impede the pedestrian are part of the practical work at Boston's Public Service School for women.

some of the subjects emphasized. Marjorie Shuler in the *American Review of Reviews* tells how Boston trains its women for specific city duties.

Registered in the school are women whose children have grown up leaving them with decreased home duties, middle-aged women with no children, widows with children to support, and women tired of routine office work. Federal, state, and municipal officials, college professors, and social workers voluntarily give their services as instructors.

Following the general course which covers the historical background of the modern city, its social structure, charter, officials, electorate, finance, and departments, the class is divided into three divisions, the class of policewomen, class for school attendance officers, and school of sanitary inspectors. The school aims to fill positions with a maximum salary of \$2,000.

The class of sanitary inspection has three sections. Tenement house inspectors hear lectures on overcrowding, light and air, plumbing and

waste disposal, trade waste, and snow removal. They learn how to deal with careless householders and ineffi-

Streets littered with refuse from overflowing ash cans are heavily scored by students of the school.

Efficient Milk Control Boon to City Health*

How Birmingham Secures a Safe Clean Milk at a 25 Per Cent Price Decrease

By L. C. BULMER, CHIEF, DIVISION OF FOOD AND DAIRY INSPECTION, BIRMINGHAM, ALA.

THERE is probably no matter discussed less in public health circles than the problem of systematizing milk control, and, progress toward the solution of the milk problem has been practically arrested in all but a few of our larger cities due to inadequate organization and slipshod administration. Almost everywhere the public has been disappointed and the dairy industry discouraged by so-called "milk control," which has not attained its fundamental object. The majority of consumers are still receiving milk of poor keeping quality, frequently watered, and of questionable safety. Milk producers look in vain for the long promised increased consumption of milk and are confronted as much as ever with unscrupulous competition of illegitimate dealers ineffectively controlled.

On the health officer who fails to recognize the significance of the milk problem in his public health policy, who tolerates a milk ordinance which is impractical, or who compromises a system of control by appointing officials who are untrained, incompetent, and frequently political "dead-heads," falls the responsibility of jeopardizing the people's right to a wholesome unadulterated supply of milk, of failure to promote better health by bringing about an increased milk consumption, and of erecting a barricade that hinders the growth and prosperity of an industry which no nation can afford to be without.

Probably not 20 per cent of our cities have what may be truly termed systematic control of their milk supply, the remainder having systems of control in various stages of disorganization. This is substantiated by a report on milk inspection, a chapter from the forthcoming report of a committee appointed to study municipal health department practice which appeared in the *American Journal of Public Health*, July, 1922. From this report and other reliable sources the following facts may be quoted:

(1) In this country there are approximately only twenty-two cities where pasteurization of all milk is

To justify the existence of a dairy division and the expenditure of public funds, statistics must be available showing the public and appropriating bodies what milk control accomplishes. Data necessary are: Complete list of milk producers and distributors including grade of milk handled; monthly scores tabulated from daily reports of sanitary condition of premises, method of handling milk and its routine bacterial and chemical composition; clear record of tuberculin tests; average quantity of milk consumed per capita; amount of dairy products other than milk consumed; fluctuations in price of milk; benefits by public from cleaner milk and increased consumption per capita; and increased sales to dairy industry.

compulsory with the exception of certified milk or a corresponding grade.

(2) Of 83 cities in the United States with population of over 100,000, 35 have less than 75 per cent of their milk supply pasteurized; 15 have less than 50 per cent pasteurized. In many cities pasteurization is practically a commercial expediency and not a health measure, for the reason that 61 of the 83 cities quoted permit the sale of raw milk that does not meet with the requirements of either certified milk or with corresponding safety standards universally recommended as essential by authorities on this subject.

(3) In spite of the recommendations of the National Commission on Milk Standards concerning the grading of milk only 31 of the cities quoted have provisions for a grading system, and even among these 31 there is little uniformity as to requirements.

(4) No figures are available concerning the number of cities in this country who publish the scores of market milk based on the sanitary conditions of the dairy premises, methods employed, and bacterial and chemical composition. The number,

however, is known to be very small. Several of the smaller cities, however, publish the scores of dairy premises, which, of course, are of no significance in regard to quality of milk distributed.

(5) Of the cities studied only 43 require the scoring of dairy farms. The number of farms per 100,000 population is approximated at 621, while the number of official inspections per annum is between one and two.

(6) The average practice is the employment of between one and two inspectors per 100,000 population.

Imagine the task that confronts a personnel of three inspectors to systematize the control of a milk supply for a city of over 200,000 consuming 15,000 gallons of milk a day, derived from 1,000 different farms, produced by 7,000 to 8,000 cows and the product from the cow to the consumer passing through the hands of one to two thousand individuals. It may be assumed that not 75 per cent of this supply is pasteurized and the cycle of operations may be taking place within a radius of anywhere from ten miles to one or two hundred miles of the city.

The duties confronting a milk control personnel are roughly these: Sanitary inspection of all farms, including the scoring of premises and methods at milking time, devoting extra attention to dairies distributing raw milk; physical inspection of cows and checking of tuberculin tests; abatement of nuisances; supervision of milk distributions, including temperature tests, sediment tests, and the collection of samples for analysis several times monthly; inspection and scoring of milk plants, milk depots, and frequently creameries and ice cream plants; supervision of the pasteurization process, and carrying out the usual routine procedure in regard to the check on shippers to milk plants; grading of all milk; issuing of milk permits to milk producers and handlers; controlling the illegitimate cow-keepers and peddlers who spring up like mushrooms overnight; supervision of milk handled in hospitals, schools, hotels and restaurants, and last, but most important of all in connection with systematic control, mak-

*Read before the International Association of Dairy and Milk Inspectors' Convention, St. Paul, Minn., October 9 to 11, 1922.

ing out of regular reports of work done and compiling thorough records in connection with data required to be filed for reference purposes. The preparation of appropriate educational literature, the drafting of plans of new dairy buildings, and the reconstruction of old premises and attending to current correspondence and clerical work are other important items that fall to the lot of a dairy division.

Each of these different functions in milk control presents a separate field which requires organizing in order that no branch is neglected. It becomes necessary to split up the work into distinct classes or branches, such as (1) inspection and scoring of dairy farms, (2) inspection and scoring of milk plants and depots, (3) routine collection of samples during distribution, (4) inspection of milk supplies handled in volume in the city, and classification of other special branches immediately the amount of work performed is large enough to necessitate routine handling.

Zone Territory

Territory to be covered should be carefully zoned according to size and work to be performed and such zones placed in charge of inspectors who may be held responsible for results accomplished. In order that there may be an intelligent interpretation of the work done, an inspector acting in a senior capacity should survey each zone as a matter of routine with the individual inspector in charge to bring about uniformity of operations, and also standardize instruction given to milk producers and handlers, scoring of farms and plants, and the technic employed in the sampling of milk.

Assuming a city to have the necessary funds, the required law and the proper personnel, success or failure of a system of milk control will depend almost entirely on the business principles involved in office management. This is true of all branches of public health administration, and it is surprising that this factor is generally disregarded above all others in milk control.

In order to justify the object of such control, the existence of a dairy division and the expenditure of public funds, statistics which will stand the "acid test" are essential. This is a matter of vital importance to the health officer, board of health, and appropriating bodies. It is of great significance to the general public and those participating in the milk business. What does our milk control accomplish, is the logical question.

To answer this question definitely and that all work may proceed methodically, a most complete system of reports and records must be kept. Information and data necessary and desirable are: A complete list revised regularly of all milk producers and distributors, including grade of milk handled; scores or ratings compiled and tabulated monthly from daily reports of the sanitary condition of the premises, method of handling milk and its routine bacterial and chemical composition; precise information of sanitary surveys of all dairy premises; clear record of tuberculin tests; average quantity of milk consumed per capita, amount of dairy products, other than milk, consumed; fluctuations in price of milk; benefits derived by the public from a cleaner milk supply and an increased consumption per capita; benefit of milk control to the dairy industry in regard to increased sales and freedom from unscrupulous competitors.

Such information is called for from time to time, but many health departments cannot furnish such data or are unable to compile annual reports based on facts. Invariably most statistics are estimated, and where no proper record system is in vogue, such information is not only erroneous and misleading but usually worthless. There are, indeed, many health departments who could tabulate all the data on file in regard to milk control on a sheet of note-paper and in consequence are obliged annually to get on an estimating jag for the purpose of manufacturing a report that is virtually a waste of printer's ink. Daily reports of every operation performed are fundamental and from these should be compiled the monthly report, which in turn will form a basis for the annual report.

The cost of the various operations and salaries of the required personnel for the branch of milk control amount to a fairly formidable bill.

The appropriation required will depend largely on the size of the personnel and also to some extent on the qualifications and experience of persons employed and milk control should be in the hands of men who have not only had public health experience, but who have also a good knowledge of agriculture, particularly the dairy industry. Unfortunately salaries paid by municipal health departments are not sufficiently inviting to attract the service of such men, while in some cities no effort is made to secure them, as the training of a dairy inspector is given secondary consideration.

Size of personnel required will be

influenced by population of the city, radius from which milk is drawn and percentage of milk supply pasteurized. It is not possible everywhere to proclaim compulsory pasteurization for such a measure in some cities is ahead of public thought and demand. This can only be changed by the actual experience of a milk-borne epidemic, or through education which takes time to assimilate. Cities demanding raw milk, however, should necessarily pay for the extra vigilance required.

I. V. Hiscock in his report on health department practice shows the appropriation utilized for milk control in this country in 1920 varied between \$0.014 to \$0.13 per capita, the average for all the cities studied being \$0.04. Hiscock and his committee intimate in conclusion that they feel an adequate allowance for milk control would be \$0.05. With all due respect to Mr. Hiscock and the committee in question, data of conditions existing in this country, which they themselves vouch for, all point to the fact that the slight increase suggested would not bring about any material improvement in the direction of better organization or additional personnel which goes with it—especially in the numerous cities where raw milk is permitted to be sold.

Milk Control in Birmingham

As an instance of this fact Birmingham, Alabama, may be quoted. Birmingham has a population of approximately 200,000 and at the time when the Hiscock committee made its investigation the health department was utilizing an appropriation of \$10,500 per annum for milk control, an expenditure amounting to approximately \$0.052 per capita. Those who were familiar with the milk supply of Birmingham at that time will substantiate the statement that the system of control was inadequate and indeed practically worthless. It was not possible then even to attempt the grading of milk, which, if such a system had been inaugurated would have merely afforded a means to milk peddlers to impose on the public. Market milk was regularly distributed containing a million or more bacteria per cubic centimeter, gross sediment was to be found in the average milk bottle, and it is not to be surprised that Birmingham consumed less milk for its size than possibly any other city in America, consumption amounting to approximately less than one-fifth pint per capita. Milk was then a product of ill repute which people avoided whenever possible.

This briefly was the situation confronting the present health officer, Dr. J. D. Dowling in 1920 who in spite of vigorous opposition on the part of raw milk dealers and certain political forces in the city, succeeded in bringing about the enactment of a milk ordinance in July 1921. This ordinance in its adaptability to meet local conditions and the fairness of its requirements and standards possibly ranks second to none among milk ordinances of this country.

Some of the developments in Birmingham in connection with the control of the city milk supply during the past fourteen months are interesting. At the instigation of the health officer during the current year, \$30,000, an appropriation of approximately 15 cents per capita is being used for milk control. The milk control staff, including two laboratory assistants, has been increased to ten, of which five are Bachelor of Science graduates in agriculture, and one is a veterinarian.

Striking headway has been made in:

(1) Milk consumption per capita has increased 100 per cent. (2) The milk business is on a firmer foundation. (3) Organization of a producers' milk pool is completed which will increase the volume of milk pasteurized from its present figure of 15 per cent to over 80 per cent. Modern requirements in sanitation and milk hygiene, which necessitate better business methods, have been instrumental in bringing about this movement. (4) A thorough system of grading milk is in vogue. (5) The average bacterial content of market raw milk has been reduced from 780,000 per c.c., which was the average for a period covering three years before the adoption of the present milk ordinance, to an average now well below 50,000 per c.c. (6) The average bacterial content of pasteurized milk over the period quoted has been reduced from 217,000 per c.c. to less than 25,000 per c.c.,—below 10,000 for October, November and December.

(7) Milk scores are published monthly as a guide to the public. These scores are based upon sanitary condition of dairy premises, methods employed in handling milk, and the average bacterial and chemical composition of not less than three samples collected from each distributor.

(8) Over 140 sterilizers equipped with 4 to 6 H.P. boilers have been installed on dairy farms. Over 90 per cent of the dairies from which the Birmingham milk supply is derived score 80 per cent or over on the U. S. Department of Agriculture score card. Further improvements record-

ed during the past few months are New barns, 8; new milk houses, 7; barns reconstructed, 25; milk houses reconstructed, 28; new sterilizers equipped with 4 to 6 H.P. boilers, 20; new sanitary toilets installed on farms, 36; toilets made fly-proof, 52. (9) Price of milk has decreased 25 per cent within the last year. Milk selling at 20 cents in 1921 now sells at 15 cents.

Benefit to health brought about by increased consumption of clean milk cannot be estimated in dollars and cents. Money saved by the purchase of milk of better keeping quality can be more nearly gauged. A family in a city, where milk control is lost sight of, squanders 15 cents many times in a year on "sour" or watered milk.

Milk control is a necessity from a business standpoint. It was estimated at one time that 22 per cent of the Birmingham milk supply was adulterated to the extent of over 10 per cent added water. The citizens were paying \$58,000 a year for water that was added to their milk supply. Fifty-eight thousand dollars per annum for milk control to eliminate adulteration and have clean milk would seem the wiser course. If such an object can be accomplished for \$30,000 a year, all the better. This matter is best left to the health officer to decide. To do otherwise may be penny wise and pound foolish.

Remove from Political Control

Milk control, as all other branches of public health, should be organized against political interference. Most politicians at heart want a contented community. They usually have sufficient private interest in a city to desire its growth and prosperity, and yet politics, as played by some politicians, is frequently the most disturbing factor, and politics in a public health system is perhaps the most disconcerting.

Public health may be compared to public safety. They go hand in hand, for both are associated with the safeguard of human life. Quick growth and industrial expansion of a city depends in large measure upon the contentment and sense of security that can be instilled into the public mind, but a community will not be contented nor settled in a city which is unsafe or unhealthy. People look for an opportunity to break the ties that hold them to a place where mortality is high and lawlessness rampant. Some politicians do not realize this, but the public should, and demand that both public health and public safety be removed from politics. When this

is done milk control will perhaps find its proper place in public health policies.

Sanitation, control of communicable diseases, and infant welfare each holds, and should continue to hold, a very important position in public health administration. The milk question is so intimately associated with communicable disease and infant welfare that to ignore it or belittle its importance in a public health policy is to court disaster.

If the people of a community are well nourished they will be stronger and better able to fight off disease. Bringing about the observance of laws of sound nutrition should be one of the chief functions at the basis of public health administration. We must, therefore, have a clean, wholesome food supply to begin with. The consumption of more milk per capita is a starting point, for milk is our ideal food. But we must have safe milk before we can recommend its increased consumption. A city will not obtain a safe milk supply until steps are taken to systematize its control. This requires more adequate funds, better milk laws, improved organization, and common sense administration.

Dr. Charles A. Powers

In the death of its president, Dr. Charles A. Powers, the American Society for the Control of Cancer has suffered a great loss. He died from apoplexy at the University Club in Denver, December 23. The loss of a man of the caliber of Dr. Powers is particularly to be deplored in a field where success must depend upon highly specialized training, and a talent for organization.

As a Major in the American Expeditionary Forces, he was made Chief of Surgical Service, spending most of his time at American Hospital No. 1, at Neuilly, France. Following this service he received a citation from General Pershing as follows:

"By his professional skill he revolutionized the surgical treatment of faces mutilated by war wounds, demonstrating to the world how to restore them to normal condition, thereby rendering conspicuous service by this great contribution in saving the lives of many French and American soldiers."

Dr. Powers was already the possessor of the Belgian Order of Leopold, the French Legion of Honor, and the *Médaille de la Reconnaissance Française*. The Distinguished Service Medal was conferred on him by posthumous reward.

Interment was in Arlington cemetery.

State Milk Survey

THE milk survey has been used effectively during recent years as a means of community diagnosis and a basis for human betterment. Two outstanding conditions have been revealed as a result of these studies, namely, (a) the machinery for safeguarding the milk supplies of many communities is entirely inadequate, and (b) the per capita milk consumption on the average is only about one-half of what it should be.

One of the most extensive studies, on a state-wide basis, was made in Kansas, May-August, 1922, by the division of foods and drugs and the public health laboratory of the state board of health, assisted by city and county officials and the state dairy department. According to the November, 1922 *Bulletin* of the Kansas state board of health, this survey was conducted in twenty cities and towns for the purpose of determining the quality of Kansas market milk and consisted of chemical, bacteriological, and sediment examination of samples of milk collected from wagons, milk depots, stores, etc., and in most cases the inspection of the dairies producing the milk or the depots or pasteurizing plants distributing it.

A portable bacteriological laboratory field set, shipped from town to town and set up in suitable rooms provided by these towns, proved its usefulness. From the results of the survey it was concluded that "bacterial counts of not to exceed 100,000 for raw milk and of not to exceed 30,000 for pasteurized milk may be made the basis of the bacterial standard for any milk supply in this state." The detailed results of the survey, with suggestions and recommendations to the citizens and officials of cities, and to the dairymen and producers, were published in the state health bulletin as an aid to the formulation of proper milk ordinances and milk control in the cities under study.

The California Dairy Council, with the aid of the state board of education and the superintendent of public instruction, and the cooperation of city superintendents, have conducted another type of milk survey to determine the number of school children who drink milk and to test the connection between milk and the progress of the school child. The supplemental report of the California school milk survey published by the California Dairy Council points out that practically uniform results were so-

cured in all the eight cities surveyed and approximately 130,000 pupils answered the questionnaire. Although the percentage varied in the different cities, the grand total of the entire survey showed that 41.82 per cent of the children received no milk regularly, 32.55 per cent received a glass of milk daily, and 25.63 per cent a pint or more daily.

The survey in Los Angeles was most complete and covered 150 schools and over 50,000 cards. Children numbering 35,384 were carefully weighed and measured and their school progress noted in connection with their age. Outstanding among the facts in this survey are the following: 4.38 per cent of the children receiving no milk were found to be over the average graduation age, while only 1.38 per cent of the milk using children who received one pint daily were over this age. 8.8 per cent of the children receiving one pint or more of milk a day, 7.9 per cent of those receiving one glass of milk a day and 6.5 per cent of the non-milk-drinking children were ahead of their normal grade.

While there may be certain inherent factors which are responsible for some of these differences and conclu-

sions should be formulated carefully, it is instructive to have such complete information of a large school population group, and it is undoubtedly true that nutritional factors, in which milk plays an important role, are of immense importance. It is also clear in general that "milk-using children can be forced in their school work with less ill effect upon their height and weight than non-milk-using children."

San Francisco to be Mecca of Medicine in June

San Francisco will be the Mecca of the medical profession in June when eight national and district conventions will be held there. American Medical Association will convene June 25 to 29; between June 21 and 30 American Society of Tropical Medicine, Radiological Society of America, and American Radium Society will assemble; California State Medical Association will meet June 22 and 23.

Automobile caravans from eastern points to San Francisco are being planned by the committee on arrangements at convention headquarters of the A. M. A. Dr. W. E. Musgrave, 806-9 Balboa building, San Francisco, is chairman. The committee will arrange sidetrips for convention delegates upon request.

A Traveling Laboratory

To aid in the protection of its summer guests, the Michigan department of health sends out a field unit consisting of a traveling laboratory with a sanitary engineer in charge, assisted by a bacteriologist, a good inspector, and a general assistant. The interior of the motor laboratory is shown above.

Genetics and Its Relation to Eugenics

Outbreeding of Defectives Does Not Improve Racial Stock

By P. W. WHITING, CHILD WELFARE RESEARCH STATION, STATE UNIVERSITY OF IOWA, IOWA CITY, IA.

IT IS now over a half a century since Gregor Mendel, a monk of Austria, after working eight years with simple character differences in garden peas, brought forth the law of heredity which bears his name. Despite the fact that for thirty years after its publication this law was unrecognized by the scientific world, the work accomplished since its re-discovery in 1900 has been so extensive and the results have increased with such acceleration that even a geneticist, a specialist in the field of heredity, is unable to keep pace with the various advancing phases of investigation.

Mendel's simple law of "unit-character" inheritance may be illustrated by two examples chosen from the writer's work. Tabby-cats frequenting any street or back yard fence can without exception be classified as either striped (Fig. 1) or blotched (Fig. 2). The difference consists essentially in the widths of the alternate bands of light and dark color running transversely down the sides and longitudinally down the back. Each of these types may vary considerably in intensity and shade of coloring and such differences as An-

"In the investigation of human heredity we are limited by long generations, few offspring, and inability to control matings. Isolation of human genetic factors is therefore usually impossible for only the more marked differences can be traced without confusion."

"From the viewpoint of racial improvement the advantages of bringing to the surface both good and bad traits cannot be questioned. The human custom of continuously outcrossing tends to keep these latent characteristics hidden. Individuals are thus spared, but the race is not fundamentally improved."

gora fur and white spotting may obscure the character to greater or less extent. In yellow cats the striped or blotched condition may usually be seen while in black and maltese it exists as a "ghost pattern."

It has been found by breeding tests that blotched when crossed to blotched will produce only blotched, while striped by striped may produce, not only striped, but occasionally blotched as well, in which case it is evident that both of the striped parents have blotched in their ancestry and are carrying it as a recessive. Blotched, the recessive, can never carry striped. Pure striped cats by pure blotched will produce all striped offspring each of which carries blotched, the recessive. Striped is then a simple character difference from blotched, its recessive alternative. There is no overlapping variation, no intermediate between striped and blotched, and we have here a simple Mendelian unit character difference.

This case is paralleled by that of the Mediterranean flour-moth, a destructive cereal pest. The common gray form (Fig. 3) acts as a simple dominant over the black mutant variety, (Fig. 4), which occurred in the writer's cultures. Black breeds true, as does also pure gray, but gray by black produces cross-bred grays similar in appearance to pure grays but giving, when bred together, three

gray to one black, or when bred to black, one gray to one black.

From these ratios the principle is derived that in the germ cells, the reproductive elements of males and females, there occur genetic factors or genes which are passed down unchanged from generation to generation, except for a very occasional mutation. Thus in pure grays the germ cells can carry the factor for gray only, in black the factor for black only, while the cross-bred or heterozygous grays would produce two sorts of germ cells as regards these color factors, one half carrying gray and one half black. Here segregation occurs. No germ cell can carry both factors which act as alternatives to each other. When crosses are made these factors are recombined by fertilization in proportions similar to those in matching two pennies. Cross-bred gray male and female would each produce two kinds of gametes in equal numbers, those carrying black and those carrying gray. The chance of black meeting black is one out of four, of gray meeting gray the same, and of black meeting gray two out of four. The offspring, therefore, would consist of black and gray

Fig. 1. Striped Cat

Fig. 2. Blotched Cat. In mating pure striped with pure blotched, all striped offspring each carrying blotched, the recessive will be produced. This illustrates a simple Mendelian unit character difference.

moths, one-fourth black, one-fourth pure gray, and one-half cross-bred gray, indistinguishable from pure gray except by breeding tests.

As in the cats, there is much variation within each color type and this variation is to a large extent at least

the consciously directed breeding check was unobtainable. Naturally those who knew most about human differences—the anthropologists and psychologists—were unconvinced, and rightly so. Gradations in form and color, as well as in the complex mental

act as a simple unit-character recessive, but in other cases modifying factors come in or the unit which determines the defect in one case may not be the same as that which determines the defect in another.

Every psychologist knows also that feeble-mindedness exists in all degrees. Surely such types as extreme idiots or imbeciles should not be classed with morons; and morons grade from the lowest type to the so-called border-line cases, or in other words to normal. Only by consciously directed breeding tests can the number of factors involved here be determined, and such tests cannot of course be applied.

While psychologists and anthropologists, then, have been leveling just criticism at the Mendelians, the latter have continued their studies. A very extensive series of experiments on rats has been carried out by Professor Castle of Harvard University. It had long been known that a certain color variety of the common rat, known as hooded, acts as a simple Mendelian recessive to the solid colored wild type.

Hooded rats have a pigmented spot on the head and this is continued to greater or less extent down the back. For the rest the animal is white. Wide variation in the extent of this pigmented hood was noticed, grading from relatively narrow to wide. Selection and in-breeding not only showed these differences to be hereditary but increased the total range considerably. Crosses of hooded with solid color showed the gametes of the hooded to be modified, "contaminated,"

Fig. 3. Gray Flour Moth.

hereditary. Gray moths, for example, if inbred, separate into true breeding types with minor differences. Some are more or less brownish or buff, others pure black-and-white gray, while still others have the base of the wings black in various degrees. Cross bands and markings vary in position and extent, but each type in its own line breeds true.

Hereditary Differences

Clearly then these differences are hereditary, but they can hardly be called unit-character differences. One would not be able to draw any line between this or that type after crossing, but all gradations occur. Unit-character differences may be traced to unit factor differences in the germ cells or gametes, and indeed to particular elements of the gametes, the chromosomes. Complicated systems of linkage have been discovered between factors, couplings, and repulsions, interference of one degree of linkage with another, and from the whole matter it is possible to build up on a purely abstract basis a system quite as intricate and yet as logical as that of chemistry. This system, moreover, derived from critical crosses and counts determining ratios in the offspring is exactly paralleled by microscopic studies of the number, size, and distribution of the chromosomes in the gametes.

In the first flush of rediscovery of Mendel's law in 1900 and for a few years thereafter, all describable differences in man, plants, and animals were thought by various groups of over-enthusiasts to be unit-character differences. This was especially true in the case of human heredity where

and emotional types, represent character differences to be sure, and very likely hereditary differences, but they are obviously not units.

Feeble-mindedness, retardation in mental development, has been represented as a simple unit-character difference acting as a recessive to normal mentality. Matings of feeble-minded with feeble-minded should then produce only feeble-minded, while matings between normal persons, each of whom has one feeble-minded parent, should produce on the average three normal to one feeble-minded. A normal from good stock mating with a feeble-minded should produce only normal, but these carry the factor for feeble-mindedness, and

Fig. 4. Black Moth.

Common gray moth acts as a simple dominant over the black mutant variety.

will produce an average of one feeble-minded to one normal when they mate with feeble-minded. It may be said that in general this conception works out well, but there are some puzzling exceptions. It is very likely that in certain cases mental retardation may

with factors introduced from the solid so that the hooded rats appearing in the second generation did not have the same grade of hooding as the originals. Had the main factor itself been modified, or was there merely exchange of other stable factors to

modify the composition of the gametes and therefore grade of hooding? The matter was debated long and ardently, but eventually the weight of experimental evidence has favored the theory of supplementary modifying factors.

It has become clear that the Darwinian principle of continuous and gradual change in the production of new types is not invalidated by Mendelian work. For if mutations are rare and discontinuous as regards any one factor, numerous factors and small but discontinuous mutations will suit the most orthodox Darwinians and are apparently approved by the most progressive Mendelians.

In order that fundamental experiments in genetics may be conducted the form chosen for investigation should have rapid generations and be easily manipulated. Since ratios play an important part in genetic work, large numbers of offspring from individual matings are also essential for exact determination of principles. If small numbers only are available much has to be inferred for scientific confirmation is lacking.

The writer has for several years been working with a small insect, the parasitic wasp, known to entomologists as *Habrobracon brevicornis* (Wesmael). This insect (a male of which is shown drinking from a drop of honey in Fig. 5), is about three millimeters in length, and produces a generation in ten days when bred in the incubator at thirty degrees centigrade.

Constant temperature is indispensable for a determination of certain types of heredity since it has been shown that temperature changes produce variation not only in expression of characteristics but in their method

of hereditary transmission as well. Shell vials are used as culture bottles which may be labelled and recorded with corresponding numbers in note books. Female wasps parasitize the caterpillars of the Mediterranean

flour moth (Fig. 6) upon which the maggots feed and grow (Fig. 7). The shrivelled caterpillar remains are then abandoned and cocoons are spun (Fig. 8).

What is known as chance in development has long been more or less

considered excellent material for a study of these factors under controlled conditions. It is hoped ultimately to apply these laws to the formation of glands governing instincts in which there appears to be much variation within the wasps.

Fig. 6. Female wasps parasitize caterpillars of the Mediterranean flour moth.

tacitly recognized by geneticists but has never been made the subject of definite experiments. Dr. Sewall Wright of the Bureau of Animal Industry of the United States Department of Agriculture, working with irregular types of spotting in mammals has devised a method for estimating the relative effect of these chance factors. External environment as well as heredity may be practically constant and yet there may be considerable variation in certain characteristics due perhaps to some slight variations in rate of growth in different regions of the embryo. Relation to gravity, slight differences of pressure on different parts, momentary variations in oxygen supply at critical periods, probably have considerable influence in determination of certain ultimate qualities or characteristics of the fully developed form. These in-

The value of genetic research as related to agriculture and stock breeding has been frequently pointed out. Selection has always played an important part in the development of new strains, and crossing of types, each of which have certain desirable characteristics which the others lack, may be followed by inbreeding, selection and crossing again. One who is conversant with genetic principles may here save much time and expense by making test crosses which will reveal the hidden constitution or latent characteristics of his material.

There is an idea common among stock breeders that, in selecting for a certain quality or characteristic, the stock which reveals this in its highest development should be the only stock retained and all others should be discarded. Such a view is pre-Mendelian in that it does not recognize the principle that various Mendelian units may be combined in one stock and that some of these units can often be obtained from strains in which the characteristic desired is poorly developed. In other words more rapid and economical progress can sometimes be made by crossing a better stock with a stock that is apparently inferior than by continuing selection in the superior stock alone.

A certain type of variation in the parasitic wasp evidently depends upon several different units and the attempt is being made to analyze these units and combine them in various ways to illustrate the practical advantage of the Mendelian principle above stated.

In the investigation of human heredity we are naturally limited by many considerations, such as long generations, few offspring, and in-

Fig. 5. This wasp which produces a generation in ten days offers good material for hereditary experiment.

fluences are for the most part so numerous and intangible that they cannot be dealt with individually, but their collective effects can be estimated by the laws of chance. In certain respects the parasitic wasps are con-

ability to control matings. The isolation of human genetic factors is therefore usually impossible for only the more marked and rare differences can be traced without confusion. On the practical side of the matter there is an occasional value in knowing that a certain undesirable trait is recessive and may be covered up if one's mate be selected from a family free from it. The children are saved but the trait is likely to be passed on and no real racial advance is made.

In reference to these latent or recessive defects the subject of cousin marriages may be mentioned. Cousin marriages are not racially harmful. Two cousins, each carrying as recessive the same hidden defect may produce children "homozygous" for it, that is, showing it. If each of the parents had married into strains free from it their children would still have possessed the defect although it would not have appeared. This holds true as well for admirable characteristics as for harmful ones and explains the fact that cousin marriages have produced geniuses as well as idiots. From the point of view of racial improvement the advantages of bringing to the surface both good and bad traits cannot be questioned. The human custom of continuously outcrossing tends to keep these latent characteristics hidden, each strain introducing dominant factors partially wanting in the other. Thus individuals are spared, but the race is not fundamentally improved.

Our keenest interest and perhaps the most practical problems center not about unit-character differences in man but about those more complicated types of heredity expressed in continuous and irregular variation. Considering such human characteristics as resistance and susceptibility to disease, variations in physical and mental endurance, initiative, industry and ambition, emotional stability and power of application, capacity for accurate or abstract thought, what we most want to know is not the exact nature of the hereditary mechanism, but simply to just what extent these conditions are dependent upon heredity and to what extent they may be controlled by environment. From a eugenic point of view, the question as to the exact number and linkage relationships, of factors responsible for susceptibility to tuberculosis is of no great practical value. It is sufficient to know to just what extent heredity is actually responsible.

Now with all the difficulties attending the Mendelian analysis of human heredity, we have in identical twins

the possibility of a very accurate measurement of the relative influence of hereditary and non-hereditary factors. Identical twins, coming as they do from one and the same fertilized egg, are endowed with exactly similar hereditary nature, barring, of course, the rare but possible occurrence of

Fig. 7. Maggots feed and grow on the caterpillars.

mutation. In fact, so complex is human heredity and so many are the factors doubtlessly involved, that it may be said without fear of contradiction that identical twins are the only people in the world with the same heredity and that no one else will ever meet his genetic double. Beginning then with a pair of twins known from the birth evidence to be identical, we may study their growth, mental and physical, their resistance to disease, or any of their serological reactions, their likes and dislikes, temp-

Fig. 8. Shriveled caterpillar remains are abandoned and cocoons spun.

eraments and interests. Whatever differences we find we may put in the non-hereditary class, as far as this particular pair of twins is concerned. Although a similar difference may in two other people be in whole or in part determined by heredity, we have here in identical twins practically ab-

solute proof of non-genetic difference and the best point of attack for the determination of relative influence of heredity and environment in the most complicated characteristics. The remarkable similarity of identical twins has been often noted, a proof of the importance of heredity.

The complicated nature of human heredity should not then, invalidate the eugenic program. Though we will be for generations and perhaps always ignorant of human hereditary mechanism, much may be inferred from experiments with lower forms. Once we suspect that any type of character variation is due to heredity, we have in selection a seemingly all-powerful method of eliminating the undesirable and increasing the desirable qualities. The newspaper eugenic ideal, represented as a sort of healthy stolid mediocrity, is not and cannot be the goal of consciously directed human evolution. Multiplicity of types abound and should likewise abound in a world of men far better than the present.

The application of the principle of selection is an educational, a social and economic, perhaps even a political rather than a genetic question. What may be called the negative phase, the prevention of the most degenerate types from reproduction is quite clear. Whether this is to be brought about by isolation or sterilization is a purely technical matter depending upon expediency. The result eugenically in either case is the same. But eugenic progress would be painfully slow, if this negative aspect alone were practised. Positive methods of encouragement of superior types to the greatest possible extent is the only method which will result in any perceptible advance.

The Joint Committee on Welfare Agencies, consisting of representatives from New York State Chamber of Commerce, Merchant's Association of New York, Brooklyn Chamber of Commerce, Queensboro Chamber of Commerce and Bronx Board of Trade, after two year's study recommends creation of a welfare council composed of delegates from groups of agencies in which all the agencies in all the boroughs of the city will be represented. Representation by functional groups of agencies rather than individual representation from each agency is considered more feasible. Such a council would be a clearing house for welfare information and the promotion of common activities, and would assist in welding together the social forces of the entire city.

Municipal Zoning and Health*

By C. V. CRASTER, M.D., HEALTH OFFICER, NEWARK, N. J.

ALL good Americans hope for a future existence in Paris, but most of us do not wait for this reward in the hereafter, making the city our Mecca in this life if we can. However much Paris attracts by reason of its social life, its spaciousness and beauty of its public spaces and buildings have appealing force. The Paris of today is the result of a considered and scientific plan first conceived by Louis XIV and carried to final accomplishment by Baron Haussmann under Napoleon III at a cost of \$265,000,000. City planning upon such a scale as this did not readily appeal to the world except Germany, which felt the need of scientific planning for its rapidly growing industrial centers.

In America, city planning and development were left largely to chance partly due to the feverish growth of business and industries and in building great American centers of industry little or no attention was paid to future needs of the infant cities. This was all the more remarkable as the wisdom of city planning had been recognized in this country during the early years of its existence. In laying out the City of Washington the first president engaged the services of a French engineer, Major Charles L'Enfant, whose plans brought into being a capital city which by the logical and beautiful arrangement of its streets, avenues, and buildings became a model for new world city planning.

With the exception of the modified gridiron plan adopted for American streets, cities of America were allowed to develop by haphazard methods. A riot of disorder in city building resulted. The future growth of our cities will be much slower than in early years which makes possible adoption of plans to retrieve damage and to bring order as far as this may be possible without too great upheaval and expenditure of vast sums as in wide schemes of city planning and re-creation.

This substitute for city planning is called zoning. Although it does not take the place of city planning the two are interdependent. While zoning cannot rectify past mistakes to any great extent, it is a conscious, intelligent effort to direct future building of the city on a well considered

plan. Like good housekeeping it provides a place for everything. Like good industrial management it plans for orderly growth and expansion of the plant. Zoning requires each owner to use his property so as not to injure his neighbor. Inasmuch as in every city there is a more or less definite tendency in building leading to segregation of residential from business and factory locations, it is the function of zoning not to prevent arbitrarily this natural grouping but to aid and guide it in the best direction. By dividing city areas into residential, business, and industrial districts, zoning seeks to encourage natural development. It protects residential neighborhoods from invasion by public garages and undesirable business enterprises. It safeguards business zones from heavy or light manufacturing and from location of nuisances in their midst. It gives manufacturing zones protected and assured tenancy.

Is Zoning Constitutional?

Municipal zoning had first to receive sanction of state legislatures which by enabling acts of various degrees of latitude authorized passing of city zoning ordinances. In all zoning laws the basis of their constitutionality is apparently contingent upon police power—the necessity for protecting health, safety, and general welfare.

Police power can be employed for zoning as well as for uniform sanitary and fire protection laws but it must be employed in relation to public health, safety, morals, and general welfare. If applied arbitrarily or for esthetic or purely sentimental purposes or with unjust discrimination the courts will not uphold the ordinance.

In two recent decisions rendered by the supreme court of New Jersey, in one case forbidding the building of multi-family houses in residential zones, and in another the fixing of a minimum height of buildings, the opinion was adverse to these ordinances, as not being in the interests of health, safety and welfare. In the former case the court ruled that limitation of the number of families permitted in a given district must be based on a certain ground area per family, and that multi-family houses could not be prohibited regardless of the size of the lot on which they were built. In the latter instance the or-

der of the court stated "you can keep a building down but you can't make it go up."

Where a zoning ordinance does not fundamentally rest upon these three great considerations it loses its authority for enforcement under the enabling act which governs the constitution of all zoning ordinances.

How far do these zoning acts concern health, either directly or indirectly? The Newark zoning ordinance may be taken as representative of this class of legislation. Newark is zoned, by the act, into four "use" districts, residence, business, light industrial, and heavy industrial. The residence zone is confined to dwelling houses but allows the establishment of professional offices, such as physicians, dentists, or musicians provided they are situated in the same dwelling or apartment. Provision is also made for hotels, churches, hospitals, clubs, philanthropic institutions, and other strictly non-business uses. All business and manufacturing is prohibited in the residence zones, so that the establishment of such undesirable businesses as public garages are automatically excluded. The business zones specially exclude all public garages except after a hearing, or any kind of manufacturing other than the manufacture of products sold at retail on the premises.

Industrial districts permit all kinds of manufacturing, including public garages, except certain specified industries which produce conditions injurious to health and comfort by reason of odors, noise, gas, or smoke. Industries of this nature are confined to the heavy industrial districts. Heavy industrial zones are located in outlying sections, as far as possible from residences of the bulk of population. Here are located the nuisance industries such as chemical manufactures and slaughterhouses. Residences cannot be built in these heavy industrial areas, the reason for which is stated by Swan as follows: "The very reasons that make it desirable to exclude factories and nuisances from residence districts apply with equal if not greater force when it comes to prohibiting erection of new dwellings in districts set aside for industrial development. If it is unhealthful for people to live near a factory isolated in residence districts it is all the more unhealthful for them to live in a home isolated in an industrial district."

*References: International Journal of Public Health, Vol. 2, No. 5, September-October, 1921, G. Benoit-Levy, p. 478. American City, July and September, 1918, August and October, 1919, and January, 1920.

In addition to the "use" districts there is a further division of the city into height zones which vary from 35 feet in residence neighborhoods to 150 feet in business or industrial localities. No building is allowed to exceed the height prescribed in the zone limits. This allows more air and light in those zones more generally devoted to residential purposes. It also secures uniformity of development and places additional safeguards against freak architecture.

An important feature of city zoning is the restriction upon area, that is, regulating and outlining the area of yards and courts and other spaces around buildings. In the Newark ordinance five "area" districts are established in which the requirement for air space is defined. This section of the law defines rear yards, side-yards, and courts and requires that "except as otherwise provided in this article every room in which persons live, sleep, work or congregate shall have at least one window or ventilating skylight opening directly either upon a street or upon a rear or side yard, outer or inner court, upon the same lot." The area districts define the amount of each lot which can be used for building purposes. This occupied area varies from 35 per cent of the lot for residential sections to 90 per cent for inner lots in industrial zones.

Another important restriction upon the area districts is the number of families permitted per acre of land. This is a wise safeguard against overcrowding and makes for more even distribution of dwellings as well as discouraging the building of multiple family dwellings upon certain areas. The number of families permitted ranges from one hundred and forty per acre in the mixed districts to twenty-five families per acre in more select residential zones.

Newark's ordinance further makes provision for the creation of a board of appeals to administer the law. This board is made up of the superintendent of buildings who is chairman, chief engineer, inspector of combustibles and fire risks, health officer, and president of the tax board.

Municipal zoning based on these principles is a municipal effort to serve the public for such a law has clearly a civic function and comes well within the requirements of protecting the health, safety, and welfare of the citizens. For health it limits congestion of population, secures better home surroundings by removing noisy and odorous businesses from residential sections, and assures proper light and ventilation in the home. It aids

the city in its fire hazard and building regulations by removing dangerous businesses to outlying sections and providing better restrictions on type of buildings. By protecting the property owner from undue depreciation of property values through unwelcome businesses or buildings, and by developing certain definite districts for various buildings or businesses, it raises property values.

The economical feature of zoning is now conceded by business men and its further value in solution of traffic problems is not to be disregarded. An attractive point for the tax payer is that such an ordinance can be passed and administered with slight expense. General adoption of these measures is therefore desirable as a first step in city planning, and cannot but make for marked improvement in the health and happiness of city populations. It is the logical reply to the modern demand for order and improved supervision over city building and development.

Garden City Examples

The garden cities of Europe are of course not possible of general adoption. The remarkable results obtained however, in the garden city of Letchworth, England, might well be studied and methods applied to American cities. In this industrial city with an area of 3,800 acres and a maximum population limit of 35,000 no dwelling can exceed two floors in height nor occupy an area of more than 25 per cent of the lot. Overcrowding thus being impossible and fresh air and sunshine available everywhere, it is not surprising that statistical rates of such a community are startling. General mortality is 5 per thousand living, and the birth rate 30 per thousand.

In city zoning as in city planning the main purpose should be to help build a city in which the citizens shall live under more pleasant and healthful surroundings than is possible where no directing plan is available to bring order out of disorder.

A program for the completion of five new hospitals before the Summer of 1924 for the use of the Veterans Bureau in caring for former service men suffering from nervous and mental diseases, has been announced by the Construction Service of the Army Quartermasters Corps. The hospitals will care for 2,000 new patients and provide quarters for 800 officers, nurses, and attendants. They are at Northampton, Mass., Chillicothe, Ohio, Knoxville, Iowa, American Lake, Wash., and Camp Custer, Mich.

Richmond Achieves Striking Statistical Results

The annual report of the bureau of health of the department of public welfare, Richmond, Va., presents evidence of concrete achievements in the control of disease perhaps as striking as those which could be reported from any other city in the United States. The crude death rate has fallen from 23.4 in 1907 to 14.6 in 1921, tuberculosis rate from 221 per 100,000 in 1906-1910 to 120 per 100,000 in 1921, and the infant mortality rate from 213 in 1907 to 100 in 1921. Rates for the year 1921 of 5.7 per 100,000 for typhoid fever, of 9.7 per 100,000 for diphtheria, of 39.3 per 100,000 for diarrhea under two, represent a really brilliant achievement for a southern city with a large colored population. Measles and whooping cough still remain serious problems and figures presented in this report emphasize anew the importance of protecting infants against these diseases, since 53 per cent of all deaths from measles and 78 per cent of all deaths from whooping cough occur in Richmond in the first two years of life.

That the reduced death rates cited above are by no means accidental but result from vigorous and intelligent application of the best resources of public health science is known to all who have watched the development of the Richmond department under Dr. E. C. Levy, first health officer and later director of public welfare, and under Dr. C. C. Hudson, the present health officer. The 1921 report indicates that the Richmond department is still developing along the most aggressive lines. Consultation service for tuberculosis, systematic Schick testing and immunization of preschool children, and organized prenatal and infant welfare work form outstanding elements in the program.

General manager C. L. Bardo, of the New Haven and Central New England Railroads announces that as soon as details can be worked out the 7,000 employees in the mechanical and electrical transmission and communication departments, together with their dependents, would be protected under a huge group policy involving nearly \$7,000,000 of life insurance. The policy includes, in addition to the life insurance, accident and health provisions. The cost of the insurance to each employee will be sixty cents a month per \$1,000 of life insurance and seventy cents a month for accident and health.

Habit Clinics for Child Mental Problems*

The Misunderstood Asocial Child Often Undermines Foundations of Family Life

By DOUGLAS A. THOM, M.D., DIRECTOR, DIVISION OF MENTAL HYGIENE, BOSTON, MASS.

CLINICS recently organized dealing with mental life of children of pre-school age, found stimuli for their inception in two distinct branches of medicine. Pediatricians, having exhausted all ordinary and many of the extraordinary measures available in medicine to combat the varied problems presented in the daily life of the child, all too frequently found that success was not obtained by treating the child's stomach for indigestion or his bowels for worms or his bladder for irritation. They appreciated the fact that his tempers and terrifying dreams were not problems of simple mechanics, and the solution of many of his problems was much too obscure and intricate to yield to therapeutic measures on a physiological level. Pediatricians, therefore, naturally turned to psychiatrists for assistance.

The psychiatrist has for a long time recognized the importance of the childhood period in the development of personality. Frequently conflicts and maladjustments of adult life have been traced to experiences of childhood. The psychiatrist realizing the value of recognizing maladjustments at four instead of at forty, was quick to grasp the opportunity of observing and studying the effect of the struggle for existence on the mental development of the child.

Clinic's Twofold Function

In his study the psychiatrist was confronted with two distinct functions of the habit clinics,—research into the psychology and psychopathology of the mental makeup of the child, and the effect of both internal and external forces upon its development, and, second, the treatment of numerous and varied clinical conditions referred by physicians in the fields of medicine, *e. g.*, bed wetting, thumb and finger sucking, persistent vomiting, refusal of food, terrifying dreams and night walking, masturbation, tempers, and various types of delinquency.

To avoid the impression that either psychiatry or psychology is a panacea for all ills to which the human flesh is heir, it must be explained that

every child seen at the habit clinic has had a thorough physical examination and has been under the care of the pediatrician and other specialists since birth. Such is the scheme under which the baby hygiene clinic operates, so that what we find in our examinations invariably represents the residue of symptoms after organic causes have been removed within the limits of modern medicine and surgery; and it is only by operating as part of well equipped medical organization that such clinics can hope to function successfully. It is perhaps a bit more pathetic to see an organic case being treated by measures which could only be successful in psychogenic cases than vice versa.

The term "habit" was selected to designate the type of clinic which we desired to organize as it was quite free from any of the undesirable associations which exist in the minds of many with the terms mental, psychic, nervous, etc. Then again, habits are so much a part of the individual that every study of personality must necessarily include habits. In fact, a study of the individual's habitual reactions is a study of personality. John Dewey states, "All habits are demands for certain kinds of activity, and they constitute the self." Habits are commonly termed bad if in the long run they operate to the disadvantage of the individual. We are prone to think of habits as something outside ourselves and foreign to our own individuality, something that has crept into our lives not only uninvited, but frequently forbidden, and we therefore assume no responsibility for their presence. Yet, as Dewey points out, "It has the hold upon us because we are the habit." Habit and desire cannot be separated.

We are not sailing over uncharted seas in the establishment of the habit clinics, but are following closely the excellent work of Drs. Campbell, Healey, Glueck, Adler, and Anderson. This unit concerns itself only with children of pre-school age. It operates in the community in which the children live in association with organizations such as settlement houses which the parents have been educated to utilize and in which their confidence has been well established. It is

closely affiliated with a very highly specialized medical organization and is not an isolated unit interested in only one aspect of the child's life. These factors will eventually operate to bring about results from the clinic which will establish its value, not only to the city of Boston, but throughout the country, it is believed.

To bring to your attention some of the definite problems it seems best to use case histories to illustrate points at hand.

Nine Year Old's Case

A few months ago a nine year old girl was brought to the clinic by a worker from one of the societies interested in children, for two definite reasons, first, because of convulsions which resembled epilepsy, and secondly, because of her precocious sex interest and sex delinquencies which had begun when the child was between five and six years of age. The episode that brought the child to the attention of the society mentioned, was the finding of an obscene picture by the patient's teacher.

Physical findings were negative except for a positive tuberculin test and the spells which resembled petit mal attacks. The gynecological examination which was made on account of the social history, indicated a certain amount of irritation of the genital organs. The child was well developed and nourished.

Mental findings graded the child one year above her mental age, which gave her an intelligence quotient of 111 on the Stanford scale. She was much interested and entered eagerly into the spirit of the tests. She graded uniformly except for particularly good rote memory and practical judgment which was below her mental age. She is in the third grade at school and capable of doing work that is above the average. The teacher considers the child very bright, but at times she states that she appears extremely dull and absent-minded.

The parents state that the patient has immoral habits, that she never seeks girl friends but is always in the company of boys and has immoral relations with them. In 1920, the child was found in a cellar with several boys of her age in what was said to

*Read before Boston University School of Education, October 9, 1922.

be a compromising position. No information was obtained regarding the grandparents of the patient, but the father is said to be a fine self-respecting man who is making every effort to do all he can for the welfare of his family. Patient's mother died four years ago, was an epileptic, and a very marked hypersexual individual. She died at the Psychopathic hospital in 1918 from toxic psychosis. The patient's father was married the second time and the stepmother seems to be a woman who is kindly and affectionate toward the child and interested in her welfare. She, however, receives but little support and encouragement from the three older married sisters in the family in matters of discipline concerning the younger children. She has found the situation impossible, and a separation has resulted, not because of any difficulty with her husband, or of inability to meet the ordinary problems concerning her household duties, but on account of the conduct of the patient, and the lack of support she receives in making any effort to change this conduct for the better.

The patient until recently lived at home with her father, stepmother, and brother John, aged 13, who attends the eighth grade. He is said to be quiet, but indulges in petty stealing, and has been arrested twice, but never sentenced. There are three older married sisters who continually interest themselves in the father's household much against the wishes of their stepmother and probably to the disadvantage of the home. The father states that none of his children have seemed normal. He has always had difficulty in bringing them up. They were delinquent, misbehaved, and had bad reputations. On the whole, there seems to be nothing obvious in the immediate household which would account for the delinquent tendencies of the children.

For the past three years, the child has interested herself in boys, although from her story she has not excluded girls as companions in her erotic indulgences. From the history it is felt that patient has been more of an influence on the environment than the environment has been upon her. The father states that since the child was three years of age she has shown an abnormal interest in sexual things and has been quite aware of her own sex feelings and how to stimulate them. When returning from the moving pictures, it seems that she remembers nothing but the sensuous aspect of the picture, frequently fabricating and interweaving

situations which have no foundations. Patient has been found on several occasions in a cellar of an unoccupied house absolutely nude with three or four boys of her own age. She tells her father in detail of what has happened, and evidences no sense of shame in speaking of the active part which she has played in these episodes.

Secure Child's Cooperation

In the doctor's office she answered all questions frankly and showed herself an extremely precocious individual having an intimate knowledge of sex affairs which could have their basis only in personal experience. She made no effort to minimize her part in these unhappy events, but expressed voluntarily a desire to overcome these hypersexual tendencies. She discussed the entire situation without embarrassment, went into minutest details, discussed her innermost thoughts and her dreams in an interesting and enlightening way. She appreciated the effort that she must make in order to overcome the cravings and desires responsible for her past difficulties. She was also anxious to develop other interests to substitute for her erotic day dreams. At no time did she blame others for her trouble, and stated that she was extremely anxious to overcome her undesirable habits in order to make it easier for her stepmother, to whom she was apparently very much attached.

The foregoing case presents two definite problems for solution, first, the convulsive tendency, and second, the precocious sex interest and sex delinquencies. Physical findings in the case are essentially negative. Mental findings indicate that the child has more than ordinary intelligence. The teacher considers her bright. The delinquent behavior may be considered accidental in origin as being continued because of hypersexual cravings. Home conditions were not ideal, yet not sufficiently different to account entirely for the strain of delinquency found in this family. Associations were not better or worse than those found in the ordinary settlement district. Nothing stands out distinctly either in the mental makeup of the child, or in the environmental conditions which we can definitely point out as the exciting factor of her present difficulties. There is nothing to indicate what the future of this child will be, or what the effect of these particular sexual experiences is to have on her and the development of her personality.

What the effect of such a series of experiences upon the development of character and personality of the child, may be is open to conjecture. The cause or reason for that particular experience in this particular case at such an immature age may well be considered as environmental or accidental. The effect of such an experience will depend upon circumstances and conditions that are as much beyond the control of the child and quite as dependent upon "happenstance" for a healthy solution, as the primary experience was dependent upon mere accident. The fact that we are dealing with a child of rather high grade mental equipment who was a bit precocious in her interests other than those of sex, is indeed fortunate, for the unhappy event can be very well assimilated and digested by the child, minimized by the parents and perhaps turned to some good purpose. On the other hand, it may be repressed so completely as to lose its own identity entirely, but appear in some quite pathological condition or definite a-social act as this case apparently did with her hysterical episodes, or the experience may be rather imperfectly repressed and continually and persistently forcing its way into consciousness, producing disintegration of the personality, as is manifested in many of the psychoneuroses of the neurasthenic and anxiety types. From a physiological point of view, it is not difficult to conceive of such experiences as sensitizing the individual to subsequent emotional experiences of a sexual nature, producing a hypersexual individual, which may result in prostitution, homosexuality, or other perversions. Notwithstanding the fact that there may be this tremendous physiological sexual drive, it is not unlikely that such an experience would produce the psychological repugnance to things sexual, the two forces combating one another and resulting in conflicts which torment and incapacitate.

While the child is passing through these experiences she needs all the help and understanding that can be rallied from those having the case in charge. The family should be given as clear an understanding of what the child is going through as our knowledge and experience can give them in order to prevent insofar as possible the methods of one family in a similar case who told the child that if she did not stop masturbating she would go insane, that every one would hate her, and that people were beginning to recognize the effects of her bad habit in her appearance. It is perhaps

much easier to wait twenty years, and then begin philosophizing about the effect of such an early sexual experience and its relation to a nervous breakdown at that time, than to get a clear, concise picture of just what is taking place when the child is passing through the series of experiences, but there is no comparison between the real value of information gained while the forces are operating, and guessing fifteen years later what actually happened and how the mental mechanisms worked and the effects it may have had on the future development of the individual.

Case X Shows Parents' Fault

The following case X is to call attention to the fact that we not only have to consider what the parents have to contend with in bringing up children, but it is frequently necessary to consider what the children have to contend with in tolerating parents.

A woman about forty years of age brought her seven year old daughter to the clinic for examination, stating that she acted like a child of four years. Notwithstanding the mother's statements, she is unable to give any concrete examples of the child's immature acts. As far as could be obtained the child has no bad habits. She sleeps and eats well, is frank and honest, would like to be affectionate if the mother would permit her, shows no cruel tendencies, and about the worst the mother could say is, "She takes up with any child she can find, regardless of creed, color or nationality. I will not stand that." The mother states that she would not permit her child to associate with the Catholic children in the neighborhood, and that the Protestant children were not good enough.

The patient appeared to be a bright, keen, alert little girl, who answered all questions quickly and accurately and manifested an interest in the examination and her surroundings. In the psychological test, she graded high, having an intelligence quotient of 98. As far as the history from the mother and the examination of the child were concerned, there seemed to be but little evidence to indicate that the child was either abnormal or unusual.

The mother was interviewed again and it was ascertained that this child was not wanted, that the mother and father had been quite happy until the birth of the patient, and she was looked upon as a stumbling block in their happiness and economic success. The father's attitude toward the child

was one of indifference. He rarely gave her any attention at all. The mother states that she is not fond of her because the child is hateful and that she always makes the mother regret being kind to her. When the mother and father are together they both ignore the child and she is sent off by herself, though not permitted to play with other children.

Further investigation of the case by the social service revealed the following facts: The mother is looked upon in the neighborhood as being different, although very affectionate toward her husband. The neighbors state that it is not infrequent to hear the mother tell the child that she hates her. It was later ascertained that within a year of the time that the patient was born, the mother was looked upon as a very desirable neighbor. About this time she went away to live with a man who had been a boarder in the house, and only returned to her husband after the authorities made complaints. Shortly after her return, patient was born. Since that time, the whole social situation has changed.

The interesting and instructive lesson in these two cases is not the physical symptoms which were so obviously demanding attention that there could be but little chance of their being ignored, but the fact that our attention is forcibly directed to the immature tendencies directly related to the mental life of the child. One case cited presents a picture of some of the unusual conditions and circumstances under which children are reared.

The most common and objectionable conditions found in the parents might be grouped roughly under the following headings: (a) the over-solicitous; (b) quick-tempered; (c) rigid and righteous; (d) worried and weary by toil; (e) work-avoiding, pleasure-loving, duty-shirking; (f) mentally deficient.

Family Influence on Child

In a more general way, the moods of the parents, their quarrels, resentful attitudes, their depressions, manner of speech, timidity of the mother, arrogance of the father, self-consciousness of a younger sister, egotism of an older brother, and the favoritism directed toward one child, or the animosity towards another, all tend toward developing a mental atmosphere which would be unhealthy to imitate.

On the other hand, cheerfulness, affection, kindly consideration, cleanliness, order, manners and speech which

are kindly even if not correct, interest and attention to the questions of the child, frankness and honesty in answering questions which will conduce to a freedom of speech and action which is not inhibited by fear of punishment or silent contempt all play their part in the development of the personality of the child, which cannot be over-estimated. The environment is found to be mirrored in the character of the child more frequently than not. Undesirable habits, in order to be eradicated or dispensed with, must be replaced by some other interest. It is not sufficient simply to build up barriers which will thwart the desire and block the emotion that acts as a driving force. This force must find a new outlet in a way compatible with the environment and with the satisfaction of the child. The child should be led, not pushed. All too frequently it is the emotions that act as a stumbling block, rather than the intellect or the will.

Substitute for Bad Habit

In order fully to dispense with undesirable habits and to form new habits, it is of paramount importance to find a motive for the rejection of the old and the acceptance of the new, that is, to substitute something for the rejected habit. The idea of the new habit must be clear in the mind of the child. It must appear to the child as a thing capable of achievement. The advantages to be gained from the development of the new habit must be presented in such a way that satisfaction will come with the striving, as well as with the accomplishment.

There is the child handicapped by undesirable habits or asocial tendencies which become more fixed and elaborate, gradually but surely reaching out to incapacitate the child for meeting the problems of every day life. Such a child becomes the dominant time-consuming blot on the family, robbing the other children of their just rights. All too frequently, such a child is the source of delinquency, poverty, and misery in her home. These reactions penetrate and contaminate the very foundations of family life. It is the appreciation and the established knowledge of these facts that has led to the founding of the habit clinics, where we hope to meet these habits while they are in the making, and not after the clay has become firmly fixed. Our accomplishments will be quicker, better, and of far more importance to the individual and society if we can meet these habits at three rather than at thirty.

Tuberculosis Patients as Health Educators*

Discharged Sufferers May Become a Prophylactic Asset in the Community

BY ROBERT J. WILSON, M.D., DIRECTOR, BUREAU OF HOSPITALS, DEPARTMENT OF HEALTH, CITY OF NEW YORK.

THE spread of tuberculosis is entirely due to the failure of those who suffer from it failing to observe precautions of personal hygiene and regulations laid down by health authorities and sanitarians for its control. The difficulty in stamping out the disease lies in the fact that the information necessary to the intelligent observations of laws and regulations must be assimilated by the sufferers of the disease, who in turn must be the ones strictly to observe the necessary precautions laid down by the law.

These sufferers from disease represent a good many different classes of individuals—from those that are highly educated to the moron. These tuberculosis sufferers fall again into the following classes:

(1) Those who innocently spread the disease through ignorance of the regulations necessary for its prevention; (2) the fairly intelligent but negligent group of patients who indolently and selfishly fail to observe the regulations after they have been instructed in them; (3) the willful type of patient who although thoroughly familiar with the procedures necessary for the protection of the public breaks the regulations knowingly and in direct violation of law. There is but one way to reach these in order that the maximum amount of precaution will be observed by them and the stamping out of tuberculosis become an assured fact, and that is through education. The mode of administering education, however, must be as varied as required by the types of individuals concerned. If the cases are mentally deficient, they must be placed under supervisory control that prevents their association with the general public. If the patients are fairly intelligent as the large mass of tuberculosis patients are, it must be assumed that the regulations preventing spread are being observed. If the patients are of the negligent type, there must be some means provided for curing them of their negligence or they must be treated as a willful, dangerous type.

If they are of a willful type, then the law should be applied to them with all the strictness that it would apply to any other type of citizen guilty of criminal negligence in the failure to prevent or in the hiding of crime.

A great deal of unnecessary sympathy has been aroused for the willful type of tuberculosis patient. The general public should recognize that the willful type of tuberculosis patient is not being punished because he suffers from a malignant and distressing disease but for the fact that he has full knowledge of the necessity of protecting those with whom he associates and places them in the danger of their lives when he can easily prevent it. The willful type of tuberculosis patient is not punished for having the disease but for willfulness in refusing to obey the law.

In the process of education of the tuberculosis patients they naturally fall into two groups: those who readily interpret the laws and regulations laid down for them and observe them, and those who seem to be unable to grasp what is intended for their good and for those with whom they associate. The condition here is somewhat like a school that teaches certain subjects either by theoretical instruction only with the student making the practical applications himself, or by the school giving theoretical instruction backed by practical demonstrations in which the student takes part. In this educational campaign to rid the world of tuberculosis, there are a certain number of the afflicted ones who do not seem to be able by any method of instruction which they may receive on the outside to grasp the ideas necessary to carry out a systematic plan of personal conduct which will prevent them from being dangerous carriers of the disease. They have to have some practical application and they get this practical application through a certain period of treatment in the hospital. In the hospital these prophylactic measures are constantly brought to their attention and whenever they violate one of the regulations, their attention is called to it. After a sufficient period of time they become almost like intelligent automa-

tions and will, after leaving the institution for a sufficient length of time, automatically observe the rules laid down for them, especially if they know that infractions of these rules will again send them to the hospital.

In considering the hospitalization of tuberculosis patients as a health measure, the spread of the disease by patients suffering from tuberculosis naturally falls into two large groups, those who observe the laws and those who do not. Hospitalization applies only to those who do not observe the laws. Further those who do not observe the laws fortunately are the willful but negligent type and these patients may again be sub-divided into two groups: those found among the poor and ignorant, or what are frequently called the "lodging house" type of cases, and the more intelligent willful type that bases his right to do as he pleases upon a wrong interpretation of his rights as a citizen.

A common excuse brought forward by tuberculosis patients when forcibly hospitalized is that they are deprived of their rights as citizens and punished when they have a disease, when, as a matter of fact, they misinterpreted their rights, mistaking license for liberty and wrongly ascribing their involuntary submission to law as being due to their physical condition and not due to their mental attitude towards the regulations which the majority of the people wish to have observed. This willful intelligent type, and the thick square-headed type, who have ideas infrequently and are usually more set upon what they get to eat and drink than upon matters of public welfare, are the hardest to deal with. There is only one intelligent treatment that I have ever seen effective for them and that is to incarcerate them in a hospital which has all the modern means of treatment—which any good hospital should have—and also to all intent and purposes, is a prison in which these people are to be placed until they have shown by their submission to regulations, and their obedience to them, that they are fit to be discharged again into the community.

For over ten years I have been in

*Reprinted from Bulletin of New York City Department of Health.

charge of the tuberculosis institutions of the department of health of the city of New York. We have maintained wards for the care of the tuberculous at Riverside hospital, North Brother Island, Kingston Avenue Hospital in the Borough of Brooklyn, and the Municipal Sanitarium at Otisville, Orange county, New York. In the strictest sense of the term, each one of these institutions has been a teaching institution, whose primary reason for existence has been the care of the tuberculous, but whose secondary reason for existence has been to teach those who are treated there how to go out and become teachers of others, both by example and talk about how they were treated and what they had to do.

At the Riverside hospital institution, we have had as high as three hundred forcibly removed individuals at one time representing for the most part the lowest type of outcast life in New York and they have had it drilled into them what they must do until like soldiers they have become automatons, a large number of whom later intelligently grasp the good that they are to do; the rest are held by fear of incarceration to observe regulations laid down for them.

At the Sanatorium at Otisville, through which thousands of patients have passed, the principal thing taught to these patients, beyond a proper regulation of personal hygiene and diet, is that they are to go out of the hospital and conduct themselves in the community in such a way as to see that none with whom they associate have any possible chance to contract the disease.

It is upon the statements that I have made in this paper that I assert that the discharged patient becomes the greatest prophylactic agent for the prevention of tuberculosis that any community can have.

"Forcible Removals" Code

In order that the reader may understand conditions under which in New York tuberculosis patients are forcibly removed, attention is called to the provision of the charter (Section 1170), of the city of New York, which provides that "Said board (of health) may remove or cause to be removed to a proper place designated by it, any person sick with a (n) . . . infectious disease and designate, provide and pay for the use of places for such persons . . . For the purpose of this section a (n) . . . infectious disease shall be one declared to be such by the board of health."

As a great many of these patients are practically homeless, this provision of Section 1170 would also apply.

"The board of health may send to such place as it may direct all . . . persons in the city not residents thereof who shall be sick of any infectious . . . disease."

Section 97 of the Sanitary Code also provides:

"Whenever an inspector of the department of health shall report in writing that any person affected with any infectious disease, under such circumstances that the continuance of such person in the place where he or she may be is dangerous to the lives or health of other persons residing in the neighborhood, the sanitary superintendent, an assistant sanitary superintendent, or the director of the bureau of infectious diseases, of the said department, upon the report of a medical inspector of the said department, may cause the removal of such persons to a hospital designated by the board of health."

On May 13, 1916, the board of health enacted the following resolution:

"That the department of health adopt a policy of compulsory detention of all vagrant consumptives (popularly known as 'the lodging house type') whose sputum is positive and who are a menace to the community."

The subsequent resolution of the board of health provided:

That the medical inspector who made the inspection should certify to his actual knowledge of the violation of the health regulations upon which the patient was to be forcibly removed.

That a patient who had been detained in the hospital for a period of three months could make an application for discharge and

That, if, after examination by the medical authorities, they endorsed his discharge on the following letter; and, that if the director of the bureau of preventable diseases, after an investigation of the home environment in which he proposed to live after discharge, found them to be satisfactory, the patient would be discharged from the institution; the form utilized being the following:

Dear Sir:—

Upon the request of the Resident Physician
I examined today
The patient has been in the institution since Weight on the day of admission was and is now

Careful physical examination today revealed a relatively quiescent state,

so that in my opinion the patient might safely leave to be taken care of by friends, providing of course, that his future home environments and the place where he will have to live are sanitary. Although there is now some activity and the sputum is positive, the patient is instructed that he has to use the necessary precautions to avoid the possibility of infecting others.

During his stay in the hospital he has complied with the rules of the institution and from the report made to me by and his assistants, I am inclined to believe that the patient will continue his conscientious conduct after his discharge from the institution.

The above named patient having been an inmate of the Riverside hospital for a period of and having received instructions in the proper care of his sputum and the rules of hygiene necessary to the protection of those associated with him, I respectfully recommend that he be discharged under the parole of the Hospital Admission Board.

Yours very truly,
..... M.D.
Attending Physician.

Anti-Epidemic Measures in Far Eastern Ports

The League Health Organization has sent one of its members, Dr. Norman White, to conduct a health inquiry in the chief ports of the Far East, such as Colombo, Singapore, Batavia, Bangkok, Saigon, Hong Kong, Kanton, Shanghai, Kiurun, Kobe, Yokohama, Vladivostok, Dairen. The precise object of the inquiry is to ascertain the incidence of the more important epidemic diseases, the methods employed for the notification of cases and deaths, for the control of the diseases, for the prevention of the spread of infection by ships, as well as the possibility of securing information and of making it speedily and readily accessible.

The Council of the League, in accepting the Health Committee's recommendation on this matter, made at the instance of Dr. Miyajima, its Japanese member, pointed out that the propagation of epidemics in the Far East was of particular concern to the Asiatic Members of the League, and that the sanitary condition of this part of the world was moreover a matter that greatly interested all other countries. The Governments of all the States concerned have promised to give every assistance to this inquiry whose results may lead to the adoption of additional preventive measures and ultimately to closer co-ordination of the efforts of the various health administrations.

Dr. Norman White's Mission is expected to last about six months.

State Council to Coordinate Health Work

State Health Council Contrasted With State Public Health Associations

BY WALTER CLARKE, ADMINISTRATIVE SECRETARY, NATIONAL HEALTH COUNCIL, NEW YORK CITY.

THE coordination of state-wide health work is a matter of concern to all health workers. In its general outlines, at least, the growth of health work in each state should parallel that of the nation, in order that the national and the state-wide agencies may be closely integrated, developing complete reciprocity. The Secretariat of the Council has been studying the tendencies in the several states, and preliminary reports giving a bird's eye view of the situation have been made for the District of Columbia and the ten states of Maine, Massachusetts, New York, Ohio, Illinois, Missouri, Kansas, New Hampshire, Vermont, and Oklahoma. At its recent meeting in Cleveland the National Health Council determined its policy regarding the coordination of state health agencies and resolved to give definite encouragement to the establishment and development of state health councils modeled after the National Health Council.

In the United States two outstanding types of situations among state voluntary health organizations have developed, those in which there is only one effective voluntary state-wide health agency, and those in which there are several. Various experiments in the direction of coordination are being tried in these different situations.

Where there is but one strong voluntary health agency a Council form of organization for coordinating activities may appear impracticable. The State Health Council, as generally understood, implies several co-equal, independent organizations joined for conferences and coordination. In those states which have but one operating private health agency (it is usually a tuberculosis society), the organization of a council would necessitate, first of all, the establishment of additional health organizations representing the fields of work not dealt with by the existing private agency. In most states this would mean the creation of social hygiene, mental hygiene, and cancer organizations which might afterwards be brought together with the Tuberculosis Society, the Red Cross, the state health department and the State Medical Society in a council.

Many people object under such conditions to creating new state-wide health agencies, believing that a single general public health organization can serve all the vital purposes. Thus in Maine a state-wide public health association has been organized upon the excellent foundation provided by the state tuberculosis society. The state tuberculosis societies frequently carry on a wide variety of health activities in addition to strictly tuberculosis work, as for example, the care and feeding of children of all ages, many features of personal hygiene of children and of adults, the encouragement of wholesome recreation and better housing. Campaigns against cancer and venereal diseases, and the promotion of mental hygiene have not been generally considered to lie within the tuberculosis program. In the real state public health association these last mentioned activities have in theory at least been added to the broad tuberculosis program and new activities making a general public health program. The state public health association contemplates the reorganization of the county tuberculosis societies in order that they can carry on, so far as may be practicable, the whole well rounded public health program.

The evident difficulties of the plan, which appears on paper so well conceived, have not yet been overcome in any case, unless one except New York where the tuberculosis and public health sections of the State Charities Aid Association are a veritable state public health association. The first and most apparent difficulty of the state public health association is financial. Seal Sale funds cannot, according to the present contracts between the National Tuberculosis Association and the branch societies in the states, be used for campaigns against cancer, venereal diseases, and for the promotion of mental hygiene. Hence funds must be obtained from other sources—not an easy task. In fact, except in the case of New York it has not yet been successfully done by a state public health association, and here only partially.

The state public health association is conceived as a single agency which

unites all the voluntary health work of the state in one organization. But the local interests of certain very important national organizations can not be merged with any state agency. For example, the Red Cross chapters of a state cannot fuse themselves with the state public health association. Their charters and their source of authority prevent the surrender of their identity and their union, either as a group or as separate units, with a state health agency. Close and helpful relations may be maintained with other state health organizations, but not actual union. This seems to represent a positive limitation to the public health association plan, one that has not yet been escaped, it being impossible for the state public health association to swallow up the Red Cross chapters and constitute, as its name would imply, the sole voluntary state-wide public health agency in a state.

A possible solution would be in a combination of the council plan and the public health association plan by which the state board of health, State Medical Society, Red Cross chapters, and the state public health association would form a state health council. Other agencies, which exist or may be organized in a state, may be included in this group, such for example, as the professional nursing societies and health officers' league. The relation of the state public health association to the State Medical Society and the State Board of Health resembles the relation to the Red Cross, in that these constitute other non-absorbable agencies. There must be an exterior alliance with them because the public health association cannot supervise their activities. The board of health and the Medical Society may be represented in the board of directors of a public health association but that must be for the purpose of directing the work of that association, and not for the purpose of uniting an official agency and the Medical Society under the banner of the public health association. This being the fact there would seem to be an advantage in organizing these limited state health councils even in those states which have already created public health associations, whether they deal with tu-

berculosis alone, or tuberculosis and other health interests.

The term "public health association" as used here is intended to mean veritable public health societies with wide programs including all major phases of health work. There are several public health associations which are simply tuberculosis societies that have changed their names, and, as the French say, "the more they change, the more they remain the same." Such public health societies have of course encountered no difficulties in arranging their lines of national affiliation, as they have remained connected solely with the parent body, the National Tuberculosis Association. But the true public health association which includes in its program cancer, social hygiene, and mental hygiene work as well as tuberculosis activities confronts some difficulties in arranging for natural lines of affiliation with national bodies. The only feasible arrangement seems to be the affiliation of the public health association with each of the specialized national organizations, at least until a closer amalgamation is accomplished through the National Health Council on a national scale. The picture of such a public health association would be a complicated one.

If the state public health association be a member of a state health council, the council may very well constitute a section of a more general group of social agencies. In any case the public health association can, with advantage, affiliate itself with the state council of social agencies, if one exists, in consideration of the numerous mutual interests of health organizations, social relief agencies, and eleemosynary and penal institutions.

As mentioned above the ideal public health association contemplates county or city public health chapters built with the local tuberculosis organization as a basis. The local unit may be divided into committees or sections to deal with each pertinent phase of local public health work. In smaller units it may not be possible to carry on all the suggested phases of public health work at one time, and in that case the emphasis may be changed from time to time to cover the several fields. The state public health association would supply the local organization with materials, expert direction and occasionally may lend personnel. If the society can employ an executive officer the operations would surely be greatly facilitated.

The most vital relation of the state public health association is doubtless with the state board of health. Where

a state health council, including the state Health Officer and the state public health association, is not practicable the state health officer ought to be an advisory member of the board of directors of the State Public Health Association itself. He could, of course, be a voting member but it would usually seem preferable not to make him responsible in that degree for a voluntary health agency which may conceivably be placed sometime in the position of supporting or even criticizing the state health officer. Advisory membership may prevent embarrassment on both sides.

Oklahoma Is Cited

In many states, something short of the real public health association described above may be advantageous—a centralizing of health work through the state tuberculosis society without, however, attempting to effect complete fusion. The machinery of the tuberculosis society might be used by other societies or committees to build up in a harmonious way their activities. The central headquarters equipment, the advice and assistance of tuberculosis society executives, might be employed for specific enterprises without any form of amalgamation—the stronger, better developed, more highly organized agency aiding the newer and weaker groups. This type of friendly cooperation is in fact quite common. Thus the Oklahoma Public Health Association, really a tuberculosis society, gave material aid to the State Cancer Committee in connection with the Cancer Week campaign, by distributing pamphlets and posters to every local tuberculosis society in the state and by urging cooperation on the part of the local societies. A state tuberculosis association being the strongest and best developed voluntary agency, may thus render invaluable aid in coordinating and promoting health work without assuming responsibility or undertaking extraordinary expenses. There would seem to be considerable advantage in such cooperation. Presumably any society that, through this assistance, grows to independent strength should be drawn into a formal state health council on a basis equal to the state tuberculosis association, or might conceivably become an operating division of the stronger and older society.

Apparently in states which have several flourishing voluntary health organizations the public health association plan is not immediately feasible, because, among other reasons, no one organization is willing to submerge completely its identity in a

somewhat hazardous experiment. What may be possible after a period of association in a state health council remains to be ascertained through experience. Possibly the state health council, as we have it in Massachusetts, may in due time lead to the public health association. The experiences of several independent health agencies operating in a state lead almost certainly, sooner or later, to some kind of formal or informal coordination. Sometimes this coordination is achieved through a larger general council of social agencies, sometimes through a state health council, and sometimes through both, with the possible ultimate objective of a single health association.

The object of a state health council, as of the National Health Council, is to promote mutual understanding and helpfulness, which involves necessarily coordination and cooperation. The state health council is formed by the association of independent state-wide organizations engaged exclusively or primarily in health work such as, for example, state societies operating in the following fields of public health work; tuberculosis, social hygiene, cancer, mental hygiene, public health nursing and child welfare. In addition to these specialized societies are included also the Red Cross, the state department of health, and the State Medical Society. Each society maintains full autonomy and liberty of action but each joins through the Council in projects of mutual interests. Each member agency of the state health council may be represented by a delegate and an alternate, usually the president and executive officer respectively.

How far a state health council can go in carrying out its projects of mutual understanding and helpfulness depends on many things, but perhaps most of all upon the available financial resources and the location of the headquarters of the several agencies. The willingness of the leaders of the several agencies to scrap, what may in some cases be impressive machinery is also a factor. It is clear in theory that efficiency can be increased and expenses reduced if all the state voluntary agencies come together in joint offices and joint office services such as purchasing, shipping and telephone. But this requires first of all a considerable belief in the virtue of team work. It also requires that at least several of the members shall find it advantageous to have their headquarters in the same city. Furthermore an initial fund is necessary in order to set

up such an arrangement, although to be sound the joint arrangement must in the long run be a source of economy.

The advantages of joint offices and services should not be limited, however, to the saving of money. It is easier for health workers to help each other and understand the problems of each other if they are closely associated, meet frequently and work together on common projects. The fear that there may be interference and meddling is doubtless a futile fear. Furthermore there is a distinct advantage to the public in having a "health headquarters," a place where all the voluntary agencies can be found together, just as there is an advantage in having a banking district, a retail district, or a theater district in a city. The fact that an organization may not stand out in conspicuous isolation under the joint office plan is more than compensated by the fact that each is more accessible to the general public and each organization gains by the publicity of the others and by the visible evidence of team work which joint offices and services give to the public.

Joint Conferences and Offices

Joint offices and services are a concrete example of an understanding and helpful spirit which, in the last analysis, constitute the vital *raison d'être* of the state health council. But team work for the promotion of public health involves more than joint offices and services and can in fact exist without either. Consideration of each other in preparing programs of work, mutual confidence regarding plans, joint action for mutually helpful legislation, coordination of field work and of financial campaigns, the collective promotion of local branch organizations, and cooperative publication enterprises do not necessarily require, but are certainly made easier, by joint offices and services. A state health council can accomplish important results even when there is no employed officer. The Massachusetts Health Council has, by its periodic conferences and by the development of good will, done an important work. But the members of the Massachusetts Council are at the same time cognizant of the limitations of a council which has no one especially assigned to carry on its work, and to place in operation policies advantageous to council members.

In order to be fully successful the ideal council should have at least a part time executive officer with a stenographer, joint offices and services and frequent interstaff conferences on

all subjects of mutual interest to the members of the council.

What should be the relation of a state health council to the state board of health, the state medical and nursing societies, the local Red Cross chapters and the several national organizations whose interests are represented in the council? And finally what should be the relation of the state health council to the National Health Council?

The interest of state health agencies in the state board of health is a vital one, and the interest of the state health officer in the voluntary health agencies of the state should also be vital. Perhaps the most important function of a private health agency is to aid public agencies in their work, to support their policies when these are right and to extend the services of public agencies as rapidly as sound procedure permits. The real relation of the state health officer to the state health council will depend upon the strength and leadership of the former; but officially he should be at least an advisory, if not a regular voting delegate.

As the prevention of disease and the promotion of health must bear a close relation to the treatment of disease so the state health council should include the state medical society in its membership. It is of the utmost importance that the medical profession should have a voice in health activities because of the part physicians play in health work and because, strategically, their professional support is necessary to the success of health activities.

The state medical society should, then, be an advisory or voting member of the state health council. The nursing profession of the state should in like manner be represented in the council, especially if there be a public health nursing organization.

It may appear somewhat difficult to arrange for Red Cross interests to be represented properly in a state health council in view of the fact that there is no intermediate organization, standing between the local chapters and the Red Cross division headquarters, which embraces the interest of several states. There is no state-wide Red Cross grouping of chapters. But in practice representation in a state health council is simple. Either the divisional manager of the Red Cross may serve as a delegate of the State Red Cross interests, as in Massachusetts, or the state supervisor of nursing, the principle health interest of the Red Cross, may serve. The Red Cross remains one of

the most important voluntary health agencies in most states and in several states it is quite the most important. Whatever adjustments or expedients are necessary, should be made in order that the Red Cross may be regularly represented in the ideal state health council.

The state health council itself has no connection with specialized national organizations such as the National Tuberculosis Association, the American Social Hygiene Association, the National Organization for Public Health Nursing, but the societies which are members of the ideal state health council should certainly be affiliated with their corresponding national agencies. This affiliation gives the state health council an indirect connection with the National Health Council of which the national specialized organizations are members. To the present time no way has been provided by which state health councils can be members of the National Health Council, but an arrangement to that end is under consideration not only for the state health councils but for the state public health associations also, in order that associate membership representation may be given to health agencies on a general state-wide basis as well as on the present basis of national organizations.

Policy of N. H. C.

It is quite as clearly advantageous to the health agencies of a nation that state-wide health activities should be coordinated as it is that the national specialized agencies themselves should be coordinated in their programs and activities. Hence the National Health Council is formulating a policy of promoting the coordination of voluntary state-wide health agencies. But as there are many difficult unsolved problems in the way of the state public health association, some of which have been pointed out in previous pages, the National Health Council has taken the position of the sympathetic observer so far as the state public health association plan is concerned, while it desires positively to promote the establishment of state health councils modeled after the National Health Council itself. It is recognized in the meantime that a state health council may eventually develop into a state public health association; but it is believed that that process will and ought to be a gradual one extending perhaps over a number of years.

Difficulties in the way of the state public health association are not altogether due to the state conditions. It will be difficult for strong state

public associations having sections devoted to tuberculosis, cancer, social hygiene, and other specialized fields to develop in advance of a parallel development on a national scale and among national organizations. The natural present tendency is for each national organization to create branch societies in each state, these branches being directly affiliated with the parent national organization and in many instances contributing to its support. But the state public health association, gathering specialized public health work under one head and management, interposes itself between the national specialized organizations and their interested state-wide groups, whether these groups be organized or not.

Were all national health organizations merged in one great national public health association the relation of such a comprehensive organization to the state public health association would be simple. As it is, there is nobody corresponding on a national scale to the state-wide public health association, and in the state public health association the national specialized public health organizations tend to lose contact with their local groups.

There is the further difficulty of securing funds for a state public health association. There is now no source of financial support which gives assurance of an adequate income of some \$20,000 to \$200,000 a year for a general state-wide health program. If Christmas Seal funds could be used for the support of general public health work, including cancer, venereal diseases, and mental hygiene, it might produce sufficient revenue, but there is no assurance that this will be possible in the near future. That too may have to await the closer amalgamation of national specialized groups.

Of the remaining difficulties which might be considered, it is the opinion of a strong group of experienced health workers that it is only by pressing forward as distinctly specialized groups that popular health movements can succeed. A "public health appeal" might fail where a "tuberculosis appeal" or a "social hygiene appeal" or a "mental hygiene appeal" now succeeds in gaining community support. The advertising and publicity values of a "public health program" are considered by many to be less than that of specialized phases of public health. In view, therefore, of the danger of substantial losses, many state and national leaders of special interest groups are slow to consent to

the union of their independent organizations in a general public health program. It has seemed advisable, therefore, that the National Health Council should not at present promote the organization of state public health associations in view of the uncertain nature of such experiments, but the Council will study with the most sympathetic interest the experiments which are now under way or which may be begun during the year.

Warning Labels Needed on Lye Preparations

Laws should be enacted compelling manufacturers of caustic alkaline preparations to place warning labels on their products, states the A. M. A. committee on lye legislation. Questionnaires sent to 1,448 esophagoscopists and surgeons brought back reports of 490 cases of accidents. More accidental deaths are caused by lye than by prussic acid, yet the infrequency of the former does not release the druggist from putting a "scare" label on prussic acid bottles.

The report of the committee (J. A. M. A., Nov. 25, 1922) states that the results of their investiga-

tions were "appalling, in showing how frequently this awful calamity befalls little children." The packers of cleansers mistakenly claim that their diluted preparations are harmless and refuse to put any warning on the packages. An attempt to correct this condition by moral suasion is useless, partly because the packers believe an unfair advantage would be given diluted preparations.

The poison statutes in most states consider only deaths, and do not take into account the life of misery that can follow the narrowing of the throat, nor of the indirect deaths by nephritic, bronchial, and other complications.

In the belief that if the public can be informed of the danger, a demand for legislation will follow, the committee is planning a campaign to secure warning labels on the caustic preparations used so commonly in the household.

The Knights of Columbus, after a two year investigation, has decided against any program for the hospitalization and treatment of the tuberculous and will undertake instead educational work on prevention.

Child Health Association

THE AIM of the Child Health Association, established in October by the merging of the Child Health Organization of America and the American Child Hygiene Association, is to create a decentralized child health union in which every agency and individual would be a member of the national body yet lose no directory power in local activities.

The association aims to stimulate, when necessary, and to strengthen in every way possible the work now being done in the local communities.

First of all, it will act as a clearing house of information on all national child health activities, a switchboard through which a newly-born organization can listen in on the experiences of its elders, through which a struggling organization can learn how best to save its time, effort, and money by avoiding recognized pitfalls.

Secondly, it will serve as a source of up-to-date, scientific information on child health, prepared by the best qualified doctors and other professional workers in this and other countries.

Thirdly, it will supply a field service composed of experts who, on request of a community, will help organize a new local health body or help

solve the problems of one already existing.

Finally, it will aim to establish standards for child health work on a sound medical basis, to eliminate waste in the practical application of these standards, to coordinate the work already being done in such a way as to avoid all duplication of effort. It is quite evident from authenticated statistics that work along these lines is not sufficient to meet the present need. America now ranks last of all nations advanced enough to have statistics on maternal mortality. It ranks sixth in infant mortality. Of its twenty-two million school children, 30 per cent are so far under standard weight as to suggest a condition of malnutrition, and three million are in urgent need of medical attention. The American people, therefore, cannot afford the loss of energy due to duplication and the consequent confusion which at present results from uncorrelated child health work. That is the fundamental reason for the amalgamation of the American Child Hygiene Association and the Child Health Organization and for the proffer of administrative help from the American Relief Administration.

Health Education Saves Thousands Yearly*

By ARTHUR J. STRAWSON, SUPERVISOR OF FIELD SERVICE, NATIONAL TUBERCULOSIS ASSOCIATION, NEW YORK CITY.

HEALTH education is one of the outstanding needs of our day, and it is assumed that the voluntary health agency, working in full cooperation with the public health agency, is approved by all who have given the matter thought. Engineers studying waste in industry discovered a great need for health education. The Hoover Committee on Elimination of Waste in Industry of the Federated Engineering societies reported that among the forty-two million persons engaged in gainful employment there is an average loss of over eight days of time or 350 million days annually. In addition to this loss of time, 500,000 of these forty-two million workers die annually, at least 250,000 from causes postponable by medical supervision, periodic physical examination, health education, and community hygiene. These lives are each worth to industry some \$5,000 annually, while medical and other special care, including special food made necessary by the final illness, cost some \$3.00 per day. When these items are added, it is found that the loss to industry from preventable illness and death is \$1,800,000,000 per year. Engineering study and estimate further find that industry could save annually \$1,000,000,000 by reasonable health education and supervision. These facts alone show the need for health education.

In the first place, executives of health associations need education for their work. Some of the most effective training courses, generally under university supervision, are those provided by the growing number of schools for social work and the short courses and special institutes being given for secretaries. Secretaries should not overlook the educational value of local, state, and national conferences, while they will be wise to study carefully the development of health work in leading health journals.

The health movement is to be congratulated upon the increasing number of full time public health officers. It is evident that they must be better trained than the part time men whom they supersede. This is no disparagement of health officers who have done their best under difficult conditions when they were obliged to earn their

living by private practice and yet were held to the management of public health matters for which they were paid the merest stipend. It is fortunate that courses leading to the degree of Doctor of Public Health are now being given by such universities as Michigan, Harvard, Johns Hopkins, Pennsylvania, Tulane, Wisconsin, and Yale, while other degrees and certificates are issued by other universities. The next step after writing into the law the provision for the full time health officer is the addition of a demand that he be fitted for his work. The state health officer in New Mexico has arranged a correspondence course for the health officers in his state while two and three day working institutes are often arranged by other state health officers for the training of their part and whole time local health officers.

Physicians will greatly appreciate the opportunity which many of the present undergraduate men are having to acquire more training in tuberculosis work and in public health matters generally than was their lot in former years. In 1916 the National Tuberculosis Association endorsed the idea of having tuberculosis wards in general hospitals while at the Atlanta, Ga., meeting of the National Nursing Associations and at the Boston meeting of the American Medical Association the project of having pavilions for the tuberculous in connection with general hospitals was approved. This means greater efficiency in the training of both physicians and nurses in work for the tuberculous. So much is the National Association impressed by this need that it is giving special attention to work with medical colleges, aiding them to develop their undergraduate tuberculosis training.

Another feature which will help physicians who graduated years ago is the development of short courses in tuberculosis diagnosis and treatment, such as that provided in the Trudeau Sanatorium at Saranac Lake, New York. The National Association has cooperated in the establishment of such a course at Colorado Springs, Colo. Physicians when taking this course may combine with their studies a brief vacation amid pleasant surroundings. Somewhat similar courses are now being arranged by several of the state tuberculosis associations in

cooperation with their own state tuberculosis sanatoria.

For undergraduate nurses, the National Tuberculosis Association has prepared "An Outline of Lectures on Tuberculosis for Nurses, Occupational Aides and Social Workers with Bibliography." Several tuberculosis associations in cities have provided a course of lectures for all undergraduate nurses in which they cover the various phases of public health. One of the most satisfactory things in this connection is the rapid development of courses in public health nursing. Such courses are given as part of the work leading to a Bachelor of Science degree at the Universities of California, Iowa, Michigan, Minnesota, Missouri, Columbia University, Western Reserve University, Universities of Oregon, Texas and Washington; while other approved courses of public health nursing are given now in cooperation with the University of Louisville, Ky., Simmons College, Boston, University of Pennsylvania, and William and Mary College.

For adults the newspaper is perhaps the greatest educator in health matters. The motion picture, stereopticon slide, radiogram, traveling health exhibit, and traveling clinic are of prime importance. The literature of public health is vast in cost, variety, and results. Thousands of public and private agencies are keeping the printing press busy. The Texas Public Health Association is using a health exhibit car and had its health education in connection with the Christmas seal sale broadcasted from every important radio station in Texas.

The seal sale, itself, has become a powerful educational factor, as is demonstrated by the fact that bond issues for health objects are voted much more readily where the Christmas seal is doing its work properly. For illustration, a \$50,000 bond issue for a tuberculosis sanatorium was recently passed by a five to one vote at Beaumont and Port Arthur, Texas, where a good local tuberculosis association has been doing health education work. Another educational method for use with adults is the portable cottage which is placed by the tuberculosis or public health association upon a lot where an adult lives who has tuberculosis and who would otherwise doubtless infect his chil-

*Read before the Medical Division of the Texas Conference of Social Welfare, Dallas, Texas, October 17, 1922.

dren. Such cottages are moved from house to house by wagon, as need arises.

More important than all of these subjects combined is the training of children in proper health habits. The National Tuberculosis Association, and its affiliated state and local as-

sociations, have enrolled 8,000,000 boys and girls who for many weeks at a stretch check themselves daily on their practice of the fundamental health habits. It teaches by doing. It is made play. It aids parents to get children to gladly obey them on health matters. By introducing honors it

develops competition in this new chivalry for health. The children, by faithful performance of duties, win one by one the titles of Squire, Knight, Knight Banneret, and Knight Banneret Constant. Attractive buttons are given them in recognition of their completed labors.

County Health Associations*

By T. J. EDMONDS, EXECUTIVE SECRETARY, IOWA TUBERCULOSIS ASSOCIATION, DES MOINES, IOWA.

A NEWS item has appeared in a number of papers in Iowa to the effect that the authorities of Jackson county have voted to establish what is known as the County Public Health Unit. This means a full-time physician with nursing and laboratory service. The article states that this action is the result of the efforts of the Jackson County Public Health Association whose President is Dr. D. N. Loose. Dr. Loose is one of the Councillors of the State Medical Society and has been president of the Jackson County Medical Society. Jackson county is a typical rural Iowa county.

This item is significant for two reasons: First, it shows the value of the county public health association, and second, it is an instance of excellent cooperation between public health workers and the medical profession and gives evidence of the effectiveness of such cooperation.

Stimulated by the Iowa Tuberculosis Association the county public health association movement has made considerable progress in Iowa in the last three years. One-fourth of the counties in the state have organizations going by the above name, and in additional two-fourths of the state there are organizations which are county-wide in scope and representative in personnel of various elements of the community and which have public health committees functioning in the same manner as county public health associations. All of these organizations are affiliated with the Iowa Tuberculosis Association and elect each a representative member on the state board of directors of the association.

Through the state headquarters these organizations have contact with other state agencies; such as, the Iowa State Medical Society, State Conference of Social Work, State Teachers Association, American

Legion, Federation of Women's Clubs, Iowa Chamber of Commerce, State Farm Bureau Federation, State Board of Health, Extension Divisions of the state colleges and the Board of Control of State Institutions.

This contact relates to legislation, publicity, health education, nursing service, questions concerning hospitalization, clinics, and other questions affecting public health.

The program of local activities is an exceedingly varied one extending from fixed activities such as public health nursing, dispensaries and clinics, preventoria, open air schools, hospital aid, down to less costly and more temporary items such as school lunches, the furnishing of measuring scales, first aid kits, diagnostic clinics, health weeks, neighborhood meetings, poster contests and other educational stimuli, Modern Health Crusade supplies, exhibits, and various informational and promotive activities.

The County Public Health Association is not a new or competing social agency in any community. It is frequently the outgrowth of the activities of some long established county organization such as a Federation of Parent-Teacher Associations. Sometimes it assumes the form of a council made up of representatives of existing agencies which have an interest in health, such as the Red Cross chapter, the County Farm Bureau, commercial bodies and clubs. Another form is that of an existing social agency such as the Social Service League or Visiting Nurse Association which has met the conditions of affiliation and has constituted itself a representative of the state association functioning in the same manner as a county public health association. It is a cardinal principle of this movement to correlate rather than duplicate efforts, and to avoid new machinery.

In discussing the relationship of these groups to the state association it should be borne in mind that the latter is practically a state public

health association in its scope of work. There is no other voluntary public health state-wide agency.

* * * *

A previous issue of THE NATION'S HEALTH contained a discussion of the field activities committee of the Iowa State Medical Society. One of the purposes of this committee is to bring the medical profession into closer alliance with the public health movement and with organizations interested in public health. Another purpose was to motivate county medical societies toward cooperation with local public health movements. The County Public Health Association plan as described above and the active participation of local physicians therein was indorsed in a recent meeting of the field activities committee and the councillors, and letters will be sent by the director of the committee, F. E. Sampson, M.D., to all county medical societies.

Georgia's child labor law which falls below federal standards of the act declared unconstitutional by the Supreme Court will probably be strengthened by the legislature which meets in June, states H. M. Stanley, labor commissioner. A survey of twenty-four Georgia factories made by the federal children's bureau revealed 315 instances of employment of boys and girls under the age of 16, working from ten to twelve hours a day, some on night shift. Georgia's state law sets 14 as the minimum age for work in factories but grants working certificates to orphans of 12 years dependent on their own labor and to 12 year old children of widows. It took ten years to get the present law on Georgia's statute books, according to the statement of Commissioner Stanley.

Dr. Haven Emerson, professor of public health administration, Columbia University, and advisory editor of THE NATION'S HEALTH, has been appointed health editor of *The Survey*.

Economics of a Full Time Health Program

County Health Departments Needed to Make Rural Equal to City Health

By WALTER M. DICKIE, M.D., SECRETARY, CALIFORNIA STATE BOARD OF HEALTH, SACRAMENTO, CALIF.

THE need for full-time county health departments in California and other Pacific Coast states is very great. At the same time, these western states probably offer greater opportunities for the achievement of results, through the organization and maintenance of full-time county health departments, than do states comprising other geographical units in other parts of the country.

Six full-time county health departments are either organized or in process of organization in California at the present time. The conditions in the average California county, operating under a part-time health program, are not widely different from similar conditions in other counties throughout the United States. Most of these counties have within their borders two or three small incorporated cities, one of which may or may not have a well organized health department, the rural portion of the county depending upon a part-time county health officer for its public health administration. Too often this official is miles away from the locality where his services are needed, and his dependence upon the practice of medicine for his living makes it im-

possible for him to attend properly to the duties of his office.

On the outskirts of every incorporated city maintaining an organized city health department, there is a "No man's Land." It is just outside of the city limits of such a municipality that the most flagrant health conditions are permitted to exist. The city health officer has no jurisdiction over this zone, and the county health officer is not inclined to interfere with the affairs of a district which, because of its more congested population, offers problems that are those of a city rather than of a rural territory. It is in this "No man's Land" that the health of children is generally without supervision. It is here that the one and two-cow dairies are conducted without regard to health conditions. It is here that all of the nuisances that have to do with faulty sewage disposal are most commonly encountered. It is in this territory that contaminated wells are so frequently found responsible for the prevalence of intestinal infection. It is within this area that peddlers are able, so often, to dispose of stocks of food supplies unfit for human consumption. While all of these and many other flagrant violations of good public health procedure exist openly, the health officer of the adjoining city can merely look on and suffer the direct results of the lack of health supervision in this outland territory over which he has no jurisdiction. The county health officer, while he may be aware of the unfortunate conditions that exist here, is generally unable, even though willing, to take any hand in bettering these conditions because of the common lack of funds and lack of interest upon the part of the county government.

The development of state and county highway systems and the increased use of the automobile have removed the isolation of the small rural community. Residents of such communities, through lack of contact with the outside world, were formerly seldom exposed to various infections, chiefly respiratory, that flourish and thrive wherever large groups of individuals are in close association. As

a result, these people possess relatively little immunity against such infections which now are often more prevalent in the rural districts than in urban centers. This fact alone emphasizes the need for protecting the health of the rural resident who is now exposed to new health risks. This protection is just as necessary as is the protection of the city dweller against the intestinal infections more frequently found in rural districts. Modern transportation, in its destruction of the isolation of the rural community, has brought old health problems into relatively virgin territory and has brought about one of the most important reasons why full-time county health departments should be developed in the West.

Another factor in the spread of communicable diseases in rural districts is the union school. The development of this type of school is also a product of newer transportation methods which have made the old time district school begin to disappear. Automobile busses now carry pupils a distance of twenty or more miles to the union grammar or high schools. New and more extensive contacts result in the more extensive spread of contact diseases. * Data compiled from reports of American Child Hygiene Association.

of these rural school children is made a matter of the utmost necessity.

California, Washington, and Oregon, because of their scenic marvels rendered so easily accessible by good roads and extensive camping facilities, attract many thousands of tourists each year. The United States Forest Service provides the best of sanitary camping facilities in the forest reserve camps, as do most of the municipalities in California. More than one and one-half million people, according to the Forest Service, visit the national forests of California annually. Fully 80 per cent of these visitors are campers. There are not nearly enough camps to provide for this summer tourist army, and there should be at least 300 more improved camps for the accommodation of vacationists who travel by automobile, not from the Pacific Coast states alone, but from all parts of the United States.

That there are acute public health problems associated with the seasonal movements of these large groups of individuals is obvious. Protection of water supplies, detection of typhoid convalescents and carriers, maintenance of strict sanitation in supervised camps, and the curbing of promiscuous camping are but few of these problems now only partly solved. The field for the full-time county health unit in this work is almost

without limitation. The need for sanitary inspection service in most of the summer resort districts and in the national parks is so great that it is apparent to these million and a half tourists, and the local residents, too, who most needs the protection that such service affords, is beginning to realize the necessity of its establishment.

In California, the large cities of Los Angeles, San Francisco, and Oakland, comprising nearly half the population of the state, determine absolutely the downward trend of the state's typhoid fever death rate. It is these cities with their organized, full-time health departments that constitute the chief factor in reducing the California typhoid mortality rate to the low figure of 4.1 per hundred thousand population in 1921. When it is considered that most community water supplies in California find their sources in surface streams, it is remarkable that the California death rate for this disease is so low. The typhoid death rates for the states of Washington, Oregon, and California are almost every year about twice as high as are similar rates for the large cities within their borders. Occasionally the typhoid fever death rate for one of these large cities approaches the higher state rate but when this occurs it can nearly always be traced to an outbreak of ty-

phoid among the residents of that city who have contracted the disease in one of the out-lying districts. In 1921 the large cities of the Pacific coast obtained typhoid fever death rates varying from 1 to 3 per one hundred thousand population. The last published rate for the United States Registration Area showed a typhoid death rate of 7.8 per hundred thousand population. Similar rates for Oregon, Washington, and California for 1920 were 4.9, 5.6 and 4.8, respectively, per hundred thousand population. A comparison of the records of these cities with the records for their respective states proves that the cities, in bringing about their low rates, are placed absolutely at the mercy of conditions existing in the surrounding rural districts. If the rural territories of Pacific coast states were as well organized from a public health standpoint as are most of their large cities, typhoid fever might be almost entirely eliminated in this part of the country. The remarkable reductions in the death rate for this disease could not have been made possible without the strong public health organizations of the larger cities. If the rural districts were provided with adequate public health machinery, through the establishment of local full-time health units, California, Oregon, and Washington should have annual typhoid fever death rates not higher than 3 per 100,000 population.

Infant Deaths Low in Cities

Washington and Oregon have the lowest infant mortality rates of any states; and the several cities, both large and small, located within these states, have, according to the American Child Hygiene Association, the lowest infant mortality rates of all cities. For three consecutive years, Seattle, San Francisco, and Portland have had the lowest infant mortality rates of all cities in the United States having populations over 250,000. Oakland and Spokane, for the past three years, have had the lowest rates of all cities having populations from 100,000 to 250,000. Berkeley, Long Beach, San Diego, and Tacoma have had, during these same years, the lowest rates for all cities having populations of 50,000 to 100,000. The California cities of Pasadena, Santa Cruz, and Richmond, as well as Astoria, Ore., and Aberdeen, Wash., have made records for obtaining the lowest infant mortality rates among those cities having populations between 25,000 and 50,000, and among cities having populations of 10,000 to 25,000.

** Data not available.

** Data compiled from Public Health Reports, U.S. Public Health Service.

While it is true that the factor of climate, with relation to the production of pure milk supplies, has something to do with bringing about these remarkably low infant mortality rates, the chief factor in bringing about these remarkable results lies in the organized effort of these municipalities in saving the lives of their infants. If the rural districts of these Pacific coast states were organized as thoroughly as are the cities, the Pacific coast could well challenge New Zealand, or any geographical unit, in the making of low infant mortality rates. The natural advantages of the Pacific coast in this respect are unusual. The stability of the climate; absence of extremes in temperature and humidity; good social conditions; educational advantages; absence of over-crowding; availability of pure milk supplies; comparative absence of the first generation of the foreign-born; and social conscience of the people are factors in the saving of infant lives on the Pacific coast.

The large cities, with their organized health departments, are setting the pace. Machinery for maternal and child care is provided in every coast city of any size while in the rural districts little or none is available. The continuation of these low records, and their further lowering, depends largely upon what these states will accomplish in the organization of full-time county health units.

The minimum unit for a full-time county health department in California consists of a full-time physician as health officer, public health nurse, sanitary inspector, and an office clerk, all of whom shall devote full time to the duties of their office. A minimum of \$10,000 a year is required in the proposed county budgets. In most counties, it is proposed that the health officer shall have complete jurisdiction over all rural and urban territory within the county. With the development of the full-time health

department idea, there is growing a spirit of community responsibility in the safe-guarding of community health.

The state is stimulating the cultivation of a spirit of local independence and is encouraging every local health department to stand upon its own feet. It is advising, assisting, stimulating, and providing expert counsel in the encouragement of all local activities for the promotion of local public health. Modern conditions must be met by modern methods. Increased opportunity for the spread of contact diseases has grown tremendously since modern methods of transportation have done away with the isolation of remote communities. The opportunities for the spread of contact diseases are vastly greater today than they were ten years ago. With a full-time health officer, public health nurse, and sanitary inspector constituting a flying squadron a large amount of preliminary epidemiological work can be accomplished before calling upon state or federal health authorities for assistance. The development of full-time health units attracts a higher grade of public health official. There is no reason why an outbreak of the more common communicable diseases cannot be brought under control through the investigations and supervision of the local department. The state, under the ideal plan, should contribute only expert technical assistance that the

• Data compiled from Public Health Reports, U.S. Public Health Service

local community is not able to provide. Direction and control in the more common communicable diseases encounter greater resistance than in epidemic conditions. While control is the concern of properly constituted health authority, really effectual preventive measures none the less hinge principally upon the good habit and consistent cooperation of an interested and sympathetic public. Public health organization in such a case is but the visible evidence of enlightened public opinion.

No organization can possibly be stronger than its weakest link. California, Washington, and Oregon are now engaged in forging strong chains in their public health organizations. With the natural advantages, such as have been enumerated, the possibilities for making life longer and happier on the Pacific coast are very great. Public opinion is supporting the development of the idea with full cooperation, and there is every reason to believe that other states must look to their laurels if they are to compete with these young western states in the promotion of a health program that means longer, happier lives for their people.

TABLE IV - TYPHOID DEATH RATES PER 100,000 POPULATION "PACIFIC COAST" STATES AND CITIES*

	San Francisco Calif.	Los Angeles Calif.	Oakland Calif.	Portland Ore.	Seattle Wash.	Spokane Wash.	Oregon	Washington	California	United States
1911	15.2	11.5	13.9	19.7	10.5	38.3		19.1	17.1	21.0
1912	19.5	15.0	13.9	17.9	8.2	20.1		13.4	16.9	16.5
1913	15.9	12.2	12.2	7.2	5.3	8.6		11.5	15.6	17.9

Digest of Sanitary and Hygienic Advance

Prophylaxis in Bakers' Itch

The etiology of dermatitis in bakers has been investigated by deJong (*Brit.M.J.*, 3237, p. 65, Jan. 13, 1923). He concludes that neither the flour nor the yeast is responsible for the irritation, which occurs only where kneading is done by hand and is not found among those who handle only flour or yeast. The condition is due to immersing the hands and arms in the salt solution added to the flour, which is about 3.6 per cent in strength. Owing to the temperature of the bakehouse and ovens the salt crystallizes on the arms of the workman, and the process of kneading works the salt crystals into the skin, setting up a dermatitis in susceptible individuals. Cure was obtained by rest from work and local treatment.

Suggested prophylaxis consists in the use of a spray of fresh water after mixing the salt solution and at periods during the kneading process.

Bayer "205" a Powerful Trypanosomicide

Of a total of nine human cases of trypanosomiasis treated with Bayer "205," Low and Manson-Bahr report (*Lancet*, ii, 5181, p. 1265, Dec. 16, 1922) that of the eight infected with *T. gambiense*, seven are in good health and that one has died of cerebral trypanosomiasis. One individual infected with *T. rhodesiense* was greatly improved, though the results are not considered conclusive. The investigators state that "we can now say of Bayer "205" that, though not infallible, it is by far the most powerful trypanosomicidal substance hitherto employed."

Correlation is Made of Efficiency Tests

Williams, (*Journal A. M. A.*, Jan. 6, 1923), reports tests made on 108 students of the University of Nevada. There was, in this group, virtually no correlation between the Sargent physical test and the Schneider cardiac test for women of the age range seventeen to twenty-three years. The rather high correlation of 0.57 previously reported Williams believes was doubtless a change result and was due to the wide age range of the group tested, or to a possible difference between men and women. The Sargent and Schneider tests do not measure the same thing. Vigor,

stamina, "pep" that Dr. Sargent refers to are not the same qualities as are measured in Schneider's test. Whether Sargent's test is a good measure of physical vigor has not been determined; likewise, the reliability of Schneider's test is not indicated by this study.

Prevention of Diphtheria

The work of the Bureau of Communicable Diseases, New Haven, Conn., during the months of September, October and November was directed in the main against diphtheria. The figures for these three months as given by Lewis (*Monthly Bull. D. of H.*, New Haven, xlix, 12, December, 1922, are

City	Cases in 1921	Cases in 1922	Case rate, 100,000
Bridgeport.....	165	158	100
Hartford.....	131	143	100
New Haven.....	118	35	20
New Britain.....	47	108	170
Waterbury.....	40	57	60

Occupational Dangers of Myopia

Histories of myopes of over three diopters between the working ages of twenty to sixty have been classified according as they were engaged in close work all day or in manners of life which did not entail habitual close work. According to Harman, (*Brit.M.J.*, 3236, p. 58, Jan. 13, 1923), no less than 53 per cent came to a time when there was an unmistakable failure of ability to carry on because of serious eyestrain. Of myopes of the same types and ages who were not engaged in continuous close work 9.4 per cent experienced a critical failure of capacity. Those having myopia engaged in close work showed the following percentage of breakdowns:

Measurement	Breakdown
3-5 Diopters	33.7%
5-10 Diopters	66.5%
Over 10 Diopters	77.4%

Cancer Mortality in Baltimore

With the exception of 1815 and 1823, deaths from cancer have been recorded in the Baltimore tables of mortality in every year since 1813 and since 1875 have been classified by the organs affected. From a study of these sources Howard (*J. A. M. A.*, lxxx, 2, p. 71, Jan. 13, 1923) believes that "a very notable, though unfortunately a not accurately determinable portion of the observed increase in crude mortality rates from malignant and other tumors in Baltimore is

readily explainable on the basis of progressive improvement in diagnosis and statistical classification, and a rise in the ratio of deaths from these causes among non-residents drawn to a medical center particularly famous for the diagnosis and treatment of these maladies." He believes that while the evidence is not sufficient to prove that there has been no actual increase in the rate of cancer for all organs, at least it renders such an increase doubtful.

It is certainly clear that cancer mortality in this city cannot have increased in anything approaching the degree indicated by the crude rates. "For cancer of the only two organs, the breast and the uterus, for which rates approaching specificity could be obtained, it has been shown that in the forty years ending in 1920, mortality has not increased, and that during the latter half of this period there has occurred a gradual but very significant decline in the death rate which, in the absence of other satisfactory explanation, it seems safe to ascribe to medical activities."

Test for Pertussis

Reisenfeld (*J.A.M.A.*, lxxx, 3, p. 158, Jan. 20, 1923) finds no specific reaction to various preparations of Bordet-Gengou bacilli injected intracutaneously to prove the presence of pertussis or a natural or acquired immunity to the disease.

This differs from the findings of Oregel (See Digest for December, 1922).

Malta Fever

The first large outbreak of Malta fever in any city in the United States occurred in Phoenix, Ariz., during the summer of 1922. The outbreak resulted from the sale of goat's milk by a high-class dairy, whereas practically all the indigenous cases previously reported in this country were directly connected with the goat-raising industry. More than thirty cases were positively diagnosed, two of them proving fatal in patients already more or less invaded by other infections.

Agglutination tests for *B. melitensis* made on scrums from 115 goats in one of the herds supplying milk to the dairy gave 18.3 per cent positives. Three of the authentic cases were typical clinically and serologically; and in two cases *B. melitensis* was recovered.

G. C. Lake calls attention (*Pub.*

Health Rep., xxxvii, 47, p. 2895, Nov. 24, 1922), to the liability of incorrect diagnosis and the probability that Malta fever is widely distributed, though unrecognized, throughout the southwestern states.

In Vivo Disinfection

Weise (*Ztschr. f. Hyg. u. Infektionskrankh.*, xc., p. 56) reports good results in wound disinfection obtained by the use of tryptaflavine, rivanol, and other substances of the acridin series. Schiemann and Baumgarten (loc. cit. pp. 247 and 284) also working at the Koch Institute, find that subcutaneous or intraperitoneal injections of these dyes may check a general septicemic infection in animals by a process of *in vivo* disinfection.

Heidelberg's Infant Mortality

Dresel and Fries (*Öffentliche Gesundheitspflege*, vii, p. 289) present the following statistics of infant mortality in various social groups of the population of Heidelberg.

Members of university circles.....	54
Professional classes	81
Officials and teachers	61
Merchants	90
Skilled laborers	156
Servants	163
Unskilled laborers	207

Meat Consumption

The accompanying chart shows the downward trend of the per capita meat consumption in the United States during the past fifteen years. (Food Animals and Meat Consumption in the U. S., Dept. Circular 241, U. S. Dept. of Agric.) Roberts states that from 1907 to 1911 the per capita consumption averaged 160.4 pounds, while for the years from 1917 to 1921 the average was 141.1 pounds.

Per capital consumption of meat, 1907-1921.

Kahn Test for Syphilis

Experience gained with over 23,000 Kahn tests, eight thousand of which have been reported to physicians parallel with the Wassermann test, leads Young (*Am. J. Pub. Health*, xiii, 2, Feb., 1923) to recommend the use of the Kahn test as a check on Wassermann reactions. The author believes that the use of both tests will help to reduce the element of skepticism associated with the older test and that such a procedure has a higher degree of accuracy than that of the Wassermann test alone.

Of the 8,070 parallel tests 93.754 per cent showed complete agreement; 5.353 per cent relative agreement; and 0.892 per cent no agreement.

Ban Books on Venereal Disease

The London correspondent of the *A. M. A. (J. A. M. A.)*, lxxx, 5, Feb. 3, 1923) states that a letter to the daily press by Sir G. Archdall Reid calls attention to the banning of books on the prevention of venereal disease in New Zealand. No bookseller will stock them unless he has a guarantee from a local physician. If such is the case, one might question the appropriateness of mentioning such a thing in a Digest of Sanitary and Hygienic Advance. "It is generally being recognized that the desire to prevent sin is one thing; a desire to secure the poisoning of the sinner quite another."

Height and Weight Ratios

The most interesting finding in a study of weight and height as an index of nutrition by Clark, Sydenstricker, and Collins (*Pub. Health Rep.*, xxviii, 2, p. 39, Jan. 12, 1923) is that 19.5 per cent of the boys were more than 10 per cent underweight by

Wood's standard, as against 28.9 per cent of the girls. Overweight also showed a larger percentage of girls who were outside the limit of 20 per cent above Wood's table, 1.3 per cent of the boys being overweight as against 3.2 per cent of the girls.

The New York Supreme Court, Dutchess County, upheld a regulation of the board of health of the city of Poughkeepsie, which in effect prohibited the sale of any milk, except grade "A" raw and certified, unless pasteurized. (*Pub. Health Rep.*, xxxviii, 3, Jan. 19, 1923.)

Cow Pox Outbreak

In October, 1922, cowpox appeared among the cows of a dairy farm in Pennsylvania and the farmer's family became infected. (*The Listening Post*, I, i, Dec. 1922, published in *Pa. Dept. of Health.*) The diagnosis, first doubted because of the rarity of the disease, was confirmed by the county medical director, a representative of the State Bureau of Animal Industry, and two representatives from the state department. No cows had been introduced into the herd within three weeks of the appearance of the lesions and it was subsequently shown that there was no cowpox in the herd from which they had been purchased.

On September 16, two boys of the family, who had until that time evaded the school vaccination law, had been vaccinated successfully. One of these boys the father called his "best milker." About two weeks after the vaccination of the boys lesions were first noticed on the teats of the cows. In a few days this condition had spread to the whole herd and to the hands of the farmer and his hired man. The younger children were apparently inoculated by the father. The nineteen months old child, who slept with his mother, had a fashion of rubbing his hands over her face. The mother developed six typical vaccination pustules extending from the point of the chin backward almost to the ear. The boys who had been vaccinated were the only ones to escape the multiple lesions.

Mercury Vapor Lamp in Diet Deficiency

Radiation with a mercury vapor quartz lamp of rats fed on a diet deficient in vitamin A. by Hune (*Lancet*, ii, 5182, Dec. 23, 1921), shows that without irradiation normal growth ceased in from seven to ten days, whereas growth in the rats receiving

irradiation continued normal for a period of thirty-five to fifty days. Efforts to revive rats that had been on the deficient diet for ninety days failed completely and the rats seemed to "go to pieces" even more quickly.

Findings of Goldblatt and Soames (loc. cit.) agree in the most essential details with those of Hume. The former believe that radiation with a mercury vapor quartz lamp cannot indefinitely act as a substitute for the fat-soluble growth-promoting factor which is a necessary element of the diet.

Industrial Morbidity

Attention is called (*Pub. Health Rep.*, Dec. 29, 1922, xxxvii, 52, p. 3202) to the wide variations in the frequency of serious morbidity in different industrial establishments.

*Includes only those cases of sickness and non-industrial accidents causing disability for eight consecutive days or longer in the year 1921.

Rates are given for twenty-seven establishments based on cases of sickness and non-industrial accident causing disability for eight consecutive days or longer in the year 1921. From the lowest rate (48 cases per 1,000 persons) to the highest rate (349 cases per 1,000 persons) is a range of more than 700 per cent and, if the first establishment which appears to have an unusually high rate is excluded, the difference between the second highest and the lowest is in excess of 360 per cent of the lowest rate.

Such wide variation indicates a field for future conquest in industrial hygiene.

Etiology of Dental Caries

An examination of carious material by McIntosh, James, and Lazarus-Barlow (*Brit. J. Exp. Path.*, iii, 3, p. 138, June, 1922.) showed constantly the presence of a definite type of bacteria. These bacteria were capable

of producing a high degree of acidity by the fermentation of carbohydrates; the average final pH value of nine different strains being 2.75, which is sufficient to decalcify teeth. Teeth left in contact with a pure culture for a prolonged period, (seventeen weeks) showed changes almost identical with those found in natural caries. This treatment consisted in keeping them for one week in a pure culture at the end of which time the teeth were transferred to sterile medium. This transfer, without additional inoculation, was repeated at the end of each week in an effort to simulate conditions in the mouth.

The authors propose to give the name *B. acidophilus odontolyticus* to this type. The organisms resemble in their resistance to and formation of acid the "acidophilus" group of Moro; biologically, however, there are several points of difference.

Transmission of Antitoxin to New Born

Intradermal diphtheria toxin reactions in one hundred mothers and new born infants have been studied by Ruh and McClelland (*Am. J. Dis. Child.*, xxx, 1, Jan., 1923). Seventy-six per cent of the mothers gave negative reactions and 24 per cent positive reactions. Seventy-nine per cent of the babies gave negative reactions and 21 per cent positive. Eight babies giving negative reactions did not receive breast milk or colostrum before the reactions were read. The grouping of the mothers and babies was: Mother and baby positive, 20; mother and baby negative, 75; mother positive and baby negative, 4; mother negative and baby positive, 1.

The workers conclude that it must be a normal function of the placenta to transmit the antitoxin bodies from mother to child and that the immunity of the child is not a result of breast feeding.

Citric-serum Medium

Tests by Greenspon (*Bull. Johns Hopkins Hosp.*, xxxiv, 383, p. 30, Jan. 1923.) indicate that citric-serum medium is definitely superior to Loeffler's serum for the cultivation and isolation of diphtheria bacilli. The reaction of this medium is adjusted to pH 6.4 by means of citric acid, which serves a dual role, in that (1) it has a differential effect, inhibiting many of the common throat organisms which cannot grow at this pH, and (2) it has a growth accelerating effect on the diphtheria bacilli to which it apparently serves as a source of carbon.

Sachs-Georgi Test

Urquhart comes to the defense of the Sachs-Georgi test (*Lancet*, i, 5186, Jan. 20, 1923). He ran parallel flocculation tests and Wassermann reactions on one thousand sera with the following results:

Flocculation test positive, Wassermann reaction positive, 221.

Flocculation test negative, Wassermann reaction negative, 759.

Flocculation test negative, Wassermann reaction positive, 10.

Flocculation test positive, Wassermann reaction negative, 10.

Two per cent of tests (20) were divergent.

The conclusions based on this series are (1) that the flocculation test gives as reliable results as the Wassermann reaction, and (2) that the flocculation test is preferable to the Wassermann reaction on account of its greater simplicity.

Experimental Measles

The following summary is presented as the result of a study of experimental measles in rabbits and monkeys by Nevin and Bittman (*J. Infect. Dis.*, xxxii, 1, Jan., 1923).

In the first series of animals the virus of measles obtained from patients with measles on the second day of the disease was passed through 4 rabbits and then produced symptoms typical of measles in a monkey.

In the second series of animals the virus obtained as stated was passed through 3 rabbits and then through 3 monkeys in which symptoms typical of measles were produced. The monkey to monkey passage eliminated any question of rash due to foreign protein.

A control monkey injected with normal human blood showed no reaction.

Effects of Inbreeding

Dr. Sewall Wright of the U. S. Department of Agriculture has conducted a lengthy experiment on The Effects of Inbreeding and Crossbreeding on Guinea Pigs. (*Nov. 15, 1922. Bulletin, U. S. D. A., No. 1090.*)

In summarizing his work Wright says "there has been an average decline in vigor in all characteristics during the course of thirteen years of inbreeding of guinea pigs, brother with sister." The decline was most marked in the infrequency and size of litter. The decline was greater in the gains after birth than in the birth weight, and greater in the percentage raised of the young born alive than in the percentage born alive.

A comparison of inbred guinea pigs with a control stock indicates that the inbreds have suffered a genetic decline in vigor in all characteristics.

The Victories of Public Health

A RECENT statistical summary¹ reviews the progress which has been made in the reduction of the death rate of New York City during the past fifty-four years; and the results accomplished, seen in this long perspective, must furnish the most case-hardened student of vital statistics with a thrill of pride.

The data of chief interest, re-calculated in the form of death rates, are as follows:

Deaths per 100,000

	1868-72	1921	Per cent reduction
All causes	27.58	11.17	60
Pulmonary Tuberculosis ..	3.82	0.89	77
Diarrheal diseases under 5 years	3.23	0.37	89
Scarlet fever	0.97	0.07	93
Diphtheria	0.86	0.16	81
Smallpox	0.54	0.00	100
Whooping cough	0.36	0.06	84
Measles	0.35	0.03	94
Typhoid Fever	0.34	0.02	94

A reduction of 60 per cent in the total death rate; of 77 per cent in the tuberculosis death rate; and of from 80 to 100 per cent in the acute com-

municable diseases—surely this is a record in which every public health worker may take profound satisfaction.

Translated into terms of individual human lives, this means that whereas there were actually 64,257 deaths in New York City in 1921, there would have been 161,150 deaths if the conditions of 1868-72 had still obtained. Nearly one hundred thousand lives saved in a single city and in a single year by the advances of science and civilization. Surely "peace hath her victories no less than war."

Henry Street Settlement and Nursing

VERY impressive were the dominant tones of achievement and promise that rang in the words of the speakers on public health and public health nursing at the ceremonials and conferences that accompanied the formal dedication of the new central administration building, presented to the Henry Street Settlement by Mrs. Jacob H. Schiff as a memorial to Mr. Schiff. Even more striking was the evidence of wide interest and warm good will offered by the press and by the audiences which, throughout the five days, thronged the building to its utmost capacity. The entire demonstration was one which proved the public regard won by the visiting nurse.

¹ Department of Health, City of New York. Condensed Annual Report for the year of 1921. Summary of Results Obtained by Fifty-Four Years of Public Health Work.

Resumés of past conditions and of the present status of health conservation, with special reference to New York, were given at the conferences; the initial steps in many efforts were recalled; comparative statistics were heard, and records given out of things well done. There were also admonitions and reminders of further advance needed in many directions, most emphatically in the field of educational preparation for varied and growing responsibilities of the public health nurse.

To those who can look back upon the past thirty years in public health nursing, the distance that has been covered is little short of amazing. The scattered early groups of from two to ten visiting or "district" nurses in our country are now a national army of over 11,000. The one first school nurse, experimentally placed in a New York City school in 1902 now has over 3,500 followers who are busy in schools all over the country. Indeed, the school nurse has become the advance guard of the public health revolutionary movement in many remote places. Where the church or dispensary first sent the nurse to its own small circle, we now have municipally controlled nurses, state nurses, and nurses under the Federal government.

Looking back, the high lights in the picture of health conservation with resulting stimulus to the extension of nursing services are: the founding, in 1912, of the Federal Children's Bureau, which has brought about extraordinary advances in the standard of care for children in the ten years of its existence; the federation, in 1912, of the public health nursing groups into the National Organization for Public Health Nursing; and the development under the American Red Cross of an immense network of nursing services to the people in rural districts and the small towns, and the stimulus given to the inception of similar work in foreign countries. With this must be linked the opening of the college and the university to the nurse who asked for higher training for the social implications of her work. This enterprise at Teachers College, still far in the lead, has been taken up by many other educational institutions which are now endeavoring to meet this urgent need.

Perhaps of all the forces within our public health nursing the most deeply and subtly influential has been the fact that by the venture of nurses into neighborhood life and their adoption of the settlement idea of reciprocity in neighborliness and, further, by their democratic basis of service freely offered, to be requested and paid for by the patient, a popular appeal has been made which was irresistible. By this simple action the

restrictions of the early associations were put aside. An intermediary was no longer necessary to bring the nurse to the patient. The ancient stigma of charity was dropped, and no limitations once fixed by caste or cult were retained. Miss Brainard in her book "The Evolution of Public Health Nursing" says, "the idea of paid service and the removal of charity revolutionized the relationship of the visiting nurse to the patient. It was the beginning of the broad community service for all which has since become available in many places." Still further, the democratic principle brought trained women into the management and direction of their own work. The vitalizing results of this may be seen on every side.

The future of public health nursing contains duties and problems that increase in complexity with the rush of modern life. The new central administration building at 99 Park Avenue, New York, will, it is hoped, help to recreate continually the inspiration needed for laborious days, and if the ideals held for it are realized, and nurses working in the field of public health may meet there and, in a congenial atmosphere, give and receive, teach and learn, the intent of its founders will be fulfilled.

The recognition of their achievements and their potentialities is expressed in the inscription on the fireplace in the beautiful assembly room:

"... Dedicated to the cause of Public Health Nursing which he (Mr. Schiff) long fostered for love of Progressive Education, Civic Righteousness and Tender Ministration."

The District vs. the County Plan of Public Health Work

A FEW years ago there was much division of opinion and considerable discussion among public health officials as to the relative value of the district health office and the county health office in the development of an effective program of health administration. Some believed that a state health administration, in extending and intensifying its field work, should take the first step by organizing district offices, with each office in charge of the health work of a group of counties; others believed that the state administration should begin the enlargement of its field work by encouraging and bringing about the development of the full time county health office; still others saw no incompatibility in the two plans for the development of field work, and refused to become greatly exercised over an issue more apparent than real. This latter group realized that if the district office was first established it would, in developing the health interests and activities of the group of counties within the dis-

strict, lead inevitably to the development on the part of the counties of some sort of full-time health government; they knew, too, that the development of county units of health work would call for a certain amount of supervision, correlation and standardizing direction for a limited number of counties, in other words, that the county plan would lead to the district plan.

Experience has verified the predictions of this latter group, namely, that in the proper development of field activities in a well organized state department of public health both the district and the county offices would be called for, and that starting at either end of the road, the county end or the district end, if we go the whole course, we shall justify, indeed, find the necessity for, both the district and county office.

The only question of practical value in public health administration which remains to be answered is this: in what order should the district and the county offices be established; which should be primary, which secondary. We believe that the weight of experience and opinion justifies the view that the county organization should precede the development of the district organization. The central bank or clearing house necessarily follows, and does not precede, the organization of local banks. Without having made a detailed study of the development of field work throughout the country, general observation impresses us with the fact that the field health service has developed much faster in those states whose primary field organization consisted of county units than in those states whose first efforts were in the direction of the district office.

The reasons why the county plan of development has proved the most satisfactory point of attack are: (1) The county is a more established, better functioning unit of government than the district, the district being more for purposes of election with respect to a relatively few offices—congressmen, judges and solicitors—than for purposes of governmental service. The arrangements for the expression of mass will and for official response to public opinion are much looser in the district than in the older, more firmly established form of county government. A county may act with a great deal more freedom of movement than a district. (2) Counties are more numerous than districts. There are more counties to which public health may be presented and sold than there are districts, in short, the field of trade is much larger. (3) The interest of the county is in a problem that lies much nearer to it than the interest of the district and its problems. The county problems are better defined and more clearly visualized. (4) Last, and most important of all, the

county idea involves the element of self help, of expenditure by the local government, whereas, the district office represents the idea of help from without, expenditure by the state. Government is more permanent and satisfactory when it is based upon the development of the interest and activity, in short, the participation of the governed, than it is when the government is furnished and paid for by some distant or outside agency.

The Germ of Typhus Fever

AN EARLIER issue of THE NATION'S HEALTH¹ contained reference to the important contributions to the problem of the etiology of typhus fever made by Dr. Wolbach and his associates in their studies at Warsaw. At a meeting of the Society for Experimental Biology and Medicine in New York on January 17, Dr. Wolbach carried his researches in this field materially further by announcing the cultivation of *Dermacentoroxenus rickettsi* (the causative organism of Rocky Mountain Spotted Fever) and the production of the disease in animals from pure cultures under carefully controlled experimental conditions. The task was accomplished by cultivating endothelial cells in vitro after the method of Harrison and using these living cells as the basic medium for the growth of the parasite. Similar studies with *Rickettsia prowazeki*, the probable cause of typhus fever, using cultures of cerebral cortex, have yielded similar results to the extent that tissue cultures of *Rickettsia* fourteen days old will cause the characteristic symptoms of typhus in guinea pigs. Actual multiplication (as distinguished from survival) has not yet been certainly demonstrated in this case. If the cultivation of *Rickettsia* and production of typhus from pure cultures finally proves successful it will constitute a contribution of first rate importance to the etiology of the communicable diseases.

Respiratory Disease in Industry

THE United States Public Health Service has recently published two reports dealing with sickness among industrial workers. These reports, while covering too small a number of workers and plants to be conclusive, are very suggestive. The first report² deals with the morbidity record of a large tire factory employing many thousand employees and covers a period of three years. In this report one of the outstanding features is the importance of respiratory dis-

1. Etiology and Pathology of Typhus. The Nation's Health, p. Adv. 36, September, 1922.

2. Disabling Sickness among Employees of a Rubber Manufacturing Establishment. Public Health Reports, xxxvii, No. 50, p. 3085, Dec. 15, 1922.

ease as a factor in both the mortality and the morbidity of the workers.

The mortality percentage for disease was headed by pneumonia 26%, influenza-pneumonia 18%, and tuberculosis 7%. The morbidity percentage for disease was headed by influenza and grippe 17%, tonsillitis 7%, colds 6% and bronchitis 4% of total lost time. Thus both in mortality and morbidity, respiratory disease led all other forms of sickness.

The second report³ deals with the incidence of serious morbidity among a group of wage earners and is compiled from statistics obtained from twenty-seven establishments. In this report is a chart showing the seasonal incidence of certain respiratory diseases, the variation showing, as might be expected, a January peak and a July valley, over a three-year period.

Respiratory disease is probably the greatest single cause of lost time now existing in industry. Because of the recent influenza epidemics, susceptibility to all diseases of this class appears to be increased. While control is very difficult, certain measures can be taken to reduce contagion.

The National Lamp Works⁴ has recently initiated the use of a spot map by which each case of contagious disease is marked on a chart of the factory showing geographically the exact position of each focus of infection.

The industrial physician may also call attention to the danger of contagion and the possibility of prevention by notices and talks. Finally, the industrial dispensary may reduce the morbidity by early treatment, sound advice, and prophylactic measures. It is to be hoped that some standard method may be developed to control the outbreaks of respiratory disease in industry during the winter months. The common cold, which in most cases is the beginning of many forms, is undoubtedly very difficult to prevent or cure. To what degree isolation would help is questionable. Most factories are loath to try an experiment involving such expense without some evidence of its probable success.

Treatment which, if started early, will surely reduce the period of disability and contagion is still to be found, and although vaccines have proved satisfactory in some cases, wholesale vaccination of an entire factory force has never been tried.

Any investigation which will throw more light on the prevention of the early forms of respiratory disease will be welcomed by industrial physicians and public health workers.

Noise as a Neglected Problem in Industrial Hygiene

AMONG the many environmental problems affecting the comfort and health of the industrial worker, none has been more neglected in the past than that of noise. The conclusions of various clinical observers in regard to the influence of noisy occupations, as reviewed by Glibert¹, are conflicting. Certain physicians report a highly abnormal frequency of deafness among railroad workers, blacksmiths, and the like—a frequency progressively increasing with increasing length of service. Other physicians report negative results; and the question of increase with length of service is obviously complicated by the normal influence of the age of the individual.

Among the most important experimental contributions to this subject are those of Wittmaach². By actual study of the influence upon guinea pigs of sound vibrations transmitted respectively, through the air and by direct contact (from a vibrating floor in the cage) this investigator found that the former had no influence and the latter a very marked influence, shown particularly in degeneration of the nerve endings in the cochlea and of the organ of Corti. Peyser³ concludes from these, and other researches that (1) a continued noise of moderate intensity, transmitted only through the air, has little or no influence upon the organ of hearing; (2) noises of short duration, but intense or very shrill, particularly if repeated, injure the organ of hearing, temporarily or permanently; (3) the transmission of noises simultaneously through the air and through vibrations communicated to the skeleton, particularly through vibrations of the ground, affect the organ of hearing definitely and seriously.

This is surely a problem in regard to which we need more light. It would be of great interest, in the first place, to have careful observations by industrial physicians as to the acuity of hearing among groups of workers of similar age employed in quiet and noisy workrooms. The scientific study of this problem must finally depend, however, upon the devising of a simple and satisfactory method of estimating the extent of the noise hazard. It would be easy to do this for a noise of specific pitch by, for example, dropping a ball mounted on a wire from various heights on to a resonant plate and determining the height from which it must fall to be heard over the noise in a given workshop; but the problems of varying pitch would seriously complicate the situation, as would subjective variations in the acuity with

which different noises are perceived. The fact that workmen accustomed to a noisy atmosphere can converse easily while a stranger cannot catch a word illustrates how diverse may be the physiological factors involved in such a study.

The Maintenance of Health Among Store Workers

ABSENTEEISM among store workers is one of the preventable wastes, whose roots lie deep in the general physical condition of the community. Evidence is rapidly accumulating to show that many of the causes of absenteeism in the industrial age have their beginnings in the uncorrected defects of the school age, or even the pre-school age.

The paper by Dr. C. A. Swan in this issue of *THE NATION'S HEALTH* brings forcibly to our attention how far preventive medical methods have been effective in one of the leading stores of the country.

On the basis of physical examination of entrants, adjustment at a suitable job is effected. Defects found are followed up and corrected. Illnesses and injuries are handled to reduce lost time. Re-examination gives confidence of health and vigor. Returns from illness are seen and chronic cases thus often discovered. The general confidence from such health supervision has markedly increased the morale. The management has found such health work pays and has steadily developed the health department.

This paper gives a standard of comparison for other stores. It demonstrates the advantage of keeping good records and studying those records intelligently, so as to apply their lesson to the future.

One more field, that of the store groups, is thus put into the reporting class. One more field is developing its health needs, the technic of meeting them and, by reducing preventable human waste, is contributing to the slow steady advance and spread of public health.

Demographic Studies in New York

STATISTICAL "Sources for Demographic Studies of New York." What a jaw breaker!

And when we say that this is the title of a ten pound book of almost undiluted tabulations of that great municipal empire's multicolored family it will be understood that this is not to be one of the season's best sellers.

But everyone is interested in his own portrait; also, the world admires courage and imagination. So we can but wonder at and praise the vision of

those who have built the sharply patterned mosaic of cosmopolitan, polyglot New York.

This truly great volume, produced under the auspices of the New York City 1920 Census Committee by the labor of that devoted statistician, Walter Laidlaw, was made possible in part by the previous publication upon the 1910 census, issued by the New York Federation of Churches, and, in part by the subsequent agreement between the chief statistician of the Population Division of the Census Bureau and the Board of Health of New York City in 1914 as to the units of uniform area, (approximately 43 acres each), the sanitary tracts by which the 1920 and every subsequent Federal census will be collected.

Here we have at last for the smallest practical permanent unit of population, all the information which in the past has been published only for whole cities, counties, or for constantly changing political units of population.

Well, what of it? How does this affect human happiness, safety, government, business, health, social organization?

Just so . . . Well, if you found that by turning to one of the pages between 2 and 918 you would find the exact facts as to age, race, sex, mother-tongue, home-ownership, and literacy of every person living within one block of you, would it not seem worth while to you if you were an insurance agent, a milk distributor, a school teacher, a visiting nurse, a settlement worker, a police captain, a minister, or a real estate agent?

The volume of tables, with its introductory monograph of the population movement in New York City and the nation since 1790, the handbook with its explanatory analysis of the original data, and the map of all boroughs of the city now used as the basis for practically all the administrative public and private health and social agencies of the community, constitute the indispensable background and statistical sources for any intelligent analysis of the innumerable undertakings in the fields of commerce, industry, transportation, government, relief, education, sanitation and recreation upon which the welfare of six million people depends.

Look it over and you'll linger among its pages because of the resemblance of New York City to a cross-section of all the world. Study it and you'll earn respect for its possibilities for answering some of the queries as to causes and effects in preventive medicine. Additional comment on this book will be found elsewhere in this issue of *THE NATION'S HEALTH*. Primarily for New Yorkers, it is a volume of national importance, a suitable mathematical counterpart to Charles Booth's "Life and Labor of the People of London."

Revamping Medical Legislation in Pennsylvania*

**New Situations Call for New Legislation,
But Educational Standards Can Be Fixed**

By FREDERICK L. VAN SICKLE, M.D., EXECUTIVE SECRETARY, MEDICAL SOCIETY OF THE STATE OF PENNSYLVANIA, HARRISBURG, PA.

THE subject of legislation has never been interesting to the average medical practitioner; and yet medical legislation is as much the business of the medical profession as is any other of the affairs outside the regular routine of practice. Every two years the Pennsylvania legislature meets, and it is seldom that a legislative session does not present problems which seriously affect the medical profession.

The present discussion has received the title, "Revamping Medical Legislation in Pennsylvania." To "revamp" is to make over an article to look like new; and this is practically what happens to Pennsylvania legislation every two years. There is not much new legislation, but there is usually an effort made so as to change the laws affecting medicine and the allied branches of the healing art that they are supposedly remade and thereby benefited. Many times that revamping proves to be a detriment, and opinions are frequently expressed to the effect that medical legislation would better be let alone. However, there are some matters which it is feasible to discuss.

In the November number of the *Pennsylvania Medical Journal*, the various topics were outlined that may receive attention during the coming session of the Legislature. During the session of 1921, the governor ap-

Medical legislative matters differ in no respect from other procedures which require expert opinion for their rational direction. Nor do health projects differ from other measures in being open to emasculation by opposing interests.

The only permanent safeguard is the enlightenment of the public which is taking place through popular health education. Meanwhile, the whole rank of the medical profession needs to become active, alert, even aggressive citizens, permitting neither faddist nor fakir to impose upon the credibility of the uninitiated.

pointed a Commission on the Reorganization of the State Government, which is to report its findings on the advisability of reconstructing the various commissions, boards, and bureaus, with a view to economy and efficiency. We are reliably informed that this commission has in mind the advisability of suggesting to the governor and the legislature the need of combining the various boards and bureaus on the examination and licensure of those who practise the various forms of the healing art which are now in existence. If this report is accepted, a bill will prob-

ably be introduced which will create in the Department of Public Instruction a division of examination, licensure, and registration of those who practise medicine, pharmacy, dentistry, and the others of the ten divisions which are now in existence in this state, and which will care for any others which may in the future apply for the privilege of practising any form of the healing art.

Several meetings have been held with the representatives of the boards and bureaus which would be affected, and the matter has been discussed at length. The medical profession and all others affected should give earnest study to this subject; and, if such a bill is presented and shows a possibility of improving the conditions now existing, it should be favored by all concerned. This will constitute one of the most important features of the medical legislative revamping of 1923.

The next important subject for revamping is the Workmen's Compensation Law, which was passed in 1915 and amended in 1919. Since the passage of the amendment which distributed compensation between the physician and the hospital in a more equitable manner, a decision has been rendered by the chairman of the workmen's compensation board which has not been well received by the industrial surgeons of the state. The case in point is the decision of Harry A. Mackey, chairman of the Board, which has made it impossible for sur-

*Read before the Sixteenth Conference of Industrial Physicians and Surgeons, Pittsburgh, Pa., November 17, 1922.

geons on the staff of a hospital to collect for services rendered to the employee while in the hospital, if the insurance carrier does not feel disposed to pay the bill without appeal. It appears that unless a contract has been entered into between the employer and the surgeon prior to the service rendered to the employee, the surgeon is unable to collect his fee. This being unfair and unjust, the Compensation Act will be revamped if possible, in this respect. There are three important points connected with this subject:

(1) The line of division between the hospital and the surgeon should be so clear and distinct that no one can misinterpret the law. The bill of the surgeon and the bill of the hospital must be entirely separated.

(2) Compensation should be granted, not only for the first thirty days, but it should be possible, in the great state of Pennsylvania with its vast resources, to pay the surgeon for his services until the patient is rendered competent to resume some form of occupation—either his regular occupation or some other light work. This legislation should be so revamped that Pennsylvania shall be on a par with her sister states in this regard.

(3) The surgeon and the hospital should receive compensation for services rendered, irrespective of whether the patient survives beyond the ten-day period or not. Industrial physicians are too familiar with that portion of the law which states that collection for services cannot be made in case of the death of the employee within the ten-day period.

There are other minor changes in the Workmen's Compensation Law from the viewpoint of the physician and surgeon that should receive attention; and probably, when this matter is taken up, these various defects will be remedied.

The Conference of Industrial Physicians and Surgeons is the ideal place from which should emanate suggestions to the medical legislative conference of Pennsylvania for amendments to the Workmen's Compensation Act. Industrial physicians particularly have had more or less experience since 1916 with this service, and suggestions coming either from individual members or from the Conference are always in order.

Physicians, as a rule, have not interested themselves in legislation; but the time is at hand when more and more of the doctors of Pennsylvania and indeed of every other state are awakening to the need of being informed and of taking an active part

in legislative affairs, medical and otherwise.

For some years past there has not been a session of the Legislature in which someone did not make an effort so to revamp the laws as to prevent the vaccination of the people of this Commonwealth to prevent smallpox. Others endeavor to prevent the use of animal experimentation, thereby curtailing the possibility of research work for humanity's sake. Still others would throw open the practice of the healing art to the illiterate, the uneducated, and almost to anyone, to practise any form of healing that he may choose, so that he may feed upon the credulity of the people of this state. It has been necessary to put up a stiff fight to prevent uneducated people from obtaining the necessary legislative control to give them boards to pass upon their qualifications that would be entirely in sympathy with the few requirements asked for. At the present, we are in the attitude of defense when any of these cults apply for permission to practise the healing art without the necessary preliminary and pre-medical qualifications.

Standards Should Be High

Every practitioner of medicine in Pennsylvania would indorse the statement that the medical profession is not antagonistic to any therapeutic measures that will really relieve or cure the ills of the human family, provided that individuals proposing to practise the art have acquired the necessary preliminary education: four years in high school, with two, or possibly three years of pre-medical instruction in college, and a three years' course in the study of the special branch which the practitioners wish to pursue—these three years to be in separate calendar years, and of at least six months' duration each. This should be the minimum standard of requirements. And yet each biennial session sees the ignorant applying for the same privileges as have been acquired by the medical student who has spent seven long, wearisome years in study!

The public at large criticizes the medical practitioner for opposing legislation asked for by these people, and impugns his motives as being antagonistic from a purely "dog-in-the-manger" attitude. Apparently no amount of explanation or discussion will make plain the professional attitude, and it seems best simply to proceed along the line of opposition until such a time as the state itself will be prepared to define the necessary requirements of

anyone who wishes to practise any form of the healing art.

We receive from people in many sections complaints about those who are practising illegally some branch of the profession for which they are not licensed. Complaint is frequently made of an osteopath administering drugs; of a nurse treating injuries in industrial cases, the attendant industrial physicians not being present; of a midwife doing obstetrical operations. Physicians are frequently appealed to for the correction of these abuses. The medical profession itself has too many glass windows in its house to be forever throwing stones at its neighbors. May we not realize the necessity of living right ourselves, purging our profession of at least the more glaring defects, visible even to the public eye—cooperating for the purpose of keeping our profession efficient? We shall then be able to convince the public of the defects of others.

It is, nevertheless, true that we should not relax in our efforts to prevent those who are incompetent from practising their arts on the people. To a certain extent, it is the province of the physician to be his brother's keeper. Being educated in the healing art, the physician should the more readily see the dangers which the public is unable to discover, and should act in the capacity of warning agent, even though his motives may be misinterpreted.

The 1923 session of the legislature, considers the subject of health centers and other forms of medical practice with which the medical profession must become acquainted. It is, therefore, the duty of every member of the Conference of Industrial Physicians and Surgeons to be so alert to the interests of organized medicine that, when the profession is informed of the introduction of such bills as affect the practice of medicine and surgery, the physicians in industry may aid in securing the passage of meritorious bills, and in rendering effective opposition to those which are prejudicial to the best interests of the people of the Commonwealth.

The University of Pennsylvania graduate school of medicine is planning a course in modern graduate medical instruction for physicians in their own towns. Dr. George H. Meeker, dean, is working on the plan whereby professors will be sent at stated intervals to lecture and conduct clinics for doctors in various parts of the state.

Causes of Absenteeism Among Store Workers*

By CHARLES A. SWAN, M.D., MEDICAL DIRECTOR, THE HALL BROTHERS COMPANY, CLEVELAND, O.

MERCANTILE health service being a comparatively recent application of preventive medicine, little information is available as to absenteeism due to illness or injury. In the mercantile establishment however, as in the manufacturing plant, one of the important functions of the medical department is to reduce the number of absentees. The percentage of employees found to be absent each day justifies a careful analysis of the factors governing this absence, and the object of this paper is to present with a few comments some of the factors causing absence in a mercantile establishment having about fifteen hundred employees.

What diseases or what symptoms most frequently cause absence? What relation does age or sex have to absenteeism? What relation does the physical condition of employees as found in routine physical examinations have to absence due to illness? If we can answer some of these ques-

high school graduates. Very few employees are at hazardous work, and, as a result, serious injuries are rare, though minor injuries are common. The large majority are doing light work indoors and the resulting lack of exercise and fresh air seems to make them susceptible to illness. Most of the absenteeism is due to illness, often minor illnesses, rather than injuries.

The chart giving a classification of the common causes of absenteeism, is based on records for a period of six months, including both winter and summer months. There are three points of particular interest in it.

(1) There is a striking predominance of acute upper respiratory infections as a cause of absence. If we could eliminate this one factor, almost 40 per cent of our absenteeism would be taken care of. (2) Considering the fact that 65 per cent of the employees are women, dysmenorrhea is less important than one would expect.

rate on account of an epidemic of acute upper respiratory infections. As the summer months are approached and the amount of illness decreases the percentage of absentees drops, reaching its lowest level in July and rising again in the fall.

With regard to the relation between sex and absenteeism, the women have an absence rate over two and a half times that of the men and the married women are absent 58 per cent more than the unmarried. One might expect, on first thought, that the frequency of absence among women, would be due to conditions peculiar to the sex, such as dysmenorrhea. However, while this is true to a certain extent, the explanation seems to be more that the women are more susceptible to all types of illness than the men, and that they are more likely than the men to consider minor illness as sufficient grounds for absenting themselves from work.

As to the relation between age and absenteeism, the employees are divided into two classes, juniors and seniors, most of the juniors being under nineteen years of age. The absent rate among the seniors is 41 per cent higher than among the juniors, the explanation probably being that the younger employees are in better physical condition and, as a result, less likely to be ill. In these days of medical supervision of school children, of nutrition classes, and of compulsory correction of minor physical defects, the younger generation is undoubtedly in better condition than the older.

We have been much interested in observing this relation between the physical condition of the employees and absenteeism. All applicants are required to have physical examinations before employment, and we have been in the habit of rating each employee according to his or her physical condition. Class A employees are in good health and have no defects of any importance. Class B includes those who have minor defects but are able to undertake any type of work. Class C is comprised of those who have more serious defects so that their physical condition has to be taken into consideration in employing them. Many of these are able to do only certain type of work and are kept under observation.

That a very definite relation exists

COMMON CAUSES OF ABSENTEEISM

MARCH 1ST TO AUGUST 31ST 1922

Chart I.—Based on a period of six months which includes both winter and summer months. Respiratory infections predominate. Injuries are seventh in importance as causative factors in absence from work.

tions, we are in a position to deal intelligently with the problem.

A mercantile establishment differs considerably from the manufacturing plant in its class of employees and the conditions under which these employees work. The employees as a group are probably better educated and are certainly more intelligent than in the average manufacturing plant. There are a number of college graduates and a great many

(3) Injuries come seventh in the list, causing less than five per cent of the absence. Furthermore, this includes injuries at home as well as while employees are at work. While a factor to be considered, it comes far from assuming the importance that it does in a manufacturing plant.

The chart giving the average percentage of employees absent each month, gives an idea of the amount of absenteeism with which one has to deal and shows the curve of seasonal variation. The month of February showed an abnormally high absence

*Read before the fifty-first annual meeting of the American Public Health Association, Cleveland, O., October 16-19, 1922.

between the physical condition of employees and absenteeism, is shown by the fact that the Class B employees, those with minor defects, show an absence rate twelve per cent higher than those who are in good physical condition. The Class C employees show an absence rate 42 per cent higher than Class A.

In other words, the employees who need dental work, have uncorrected errors of refraction, are more than 15 per cent over or underweight, or have some other defect that many people would consider unimportant, are sick oftener and therefore absent more, than those who are in good physical condition. The relationship seems to be indirect rather than direct, as the disability does not cause the absence except that it makes him more susceptible to illness.

The employees who have organic heart lesions, hernias, or other more serious defects, are absent 42 per cent more than those in good physical condition, and the relationship here is also to a large extent indirect, the disability as a general rule, not being the direct cause of absence. By a simple computation, we find that, if all of our employees had defects corrected, which is possible with the large majority, the days of absence per year would be reduced by over two hundred and seventy.

Those who are making physical examinations and rarely rejecting except on the grounds of contagious disease, may meet with employers who consider physical examinations of value only if those who have defects are rejected. We certainly meet with applicants for positions who believe that the examinations are made with the idea of accepting only those who are in the best physical condition. To these people one should explain that the purpose of the examination is to discover those who are not in good health, or, who have physical defects, and, not to reject them, but to advise them, so that they may improve their health or have defects corrected. When these people can be shown from actual statistics, that the person who is in good physical condition, is absent from work less, has less sickness, there is an argument for the correction of defects that has considerable force.

A good deal of importance should evidently be attached to this relationship between absenteeism and the physical condition of the employees, but there are two reasons why there is not even a greater difference between the amount among those who have defects. First, certain injuries and ill-

nesses affect a large number of employees regardless of their physical condition. Second, individual attitudes towards bodily discomfort vary greatly.

We have been attempting to differentiate between preventable and un-

preventable causes of absence, and, in a period of six months, we have found about six hundred out of three thousand days of absence due to unpreventable causes. The attitude of the individual towards bodily discomfort, is a factor on which we cannot place too much stress. We have all seen every class of individual from the person who would like to work when he has fever and should be at home in bed, to the person who stays at home every time he has a headache or some other minor discomfort. Let us hope that some day some clever industrial physician will devise a means of discovering the latter class at the time of physical examination.

Mental hygiene has a very definite place in the solution of the problem of absenteeism. The cultivation in the individual of a healthy mental attitude towards any symptoms, minor or major, that he may have, is of inestimable value. Worry, anxiety, all these mental factors, have their effect on the health of the individual also, and, as a result, on the amount of time he loses from work.

It is evident that efforts to reduce absenteeism should follow along two lines; (1) the prevention of illness and injuries, and (2) improvement of the physical condition of the employees. Our most important problem in the prevention of illness is prevention of upper respiratory infections. Early and energetic treatment has been found to be of the greatest value. In connection with physical defects, the thoroughness of the phys-

ical examination is not as important as the thoroughness of the follow up system. All of those who are not in first class physical condition should be followed up and every effort made to have defects corrected.

Working along these lines we feel

PERCENTAGE OF EMPLOYEES ABSENT FEB 1ST TO SEPT 30TH

Chart II.—Seasonal variation in absenteeism is strikingly shown on this chart. An epidemic condition in February is to be taken into account.

that definite results can be accomplished, and, as the absenteeism is reduced, the value of the medical service is demonstrated.

The city of Calais, France, has started a municipal dairy and dairy farm, the milk from which is to be tested by health officers and the cows fed scientifically to keep the quality up to that prescribed for young babies.

Dr. H. S. Cumming, Surgeon-General of the United States Public Health Service, has been invited to join the League of Nation's hygiene committee. Dr. Cumming will also be asked to approve the plan of an international sanitary bureau with headquarters in Washington, to cooperate with the hygiene committee of the League.

Trafficers in drugs are made liable to \$500 to \$5,000 fine and one to ten years' imprisonment under terms of bill introduced into the House of Representatives Feb. 3 by Lineberger (rep., Cal.). Worldwide limitation of narcotic drug production was urged in resolution by Porter (rep., Pa.), chairman of foreign affairs committee.

Letters have been sent to all physicians in Maryland by the state board of health containing a copy of a law passed at the last session of the legislature conferring on individual physicians the powers of a county health officer in cases of emergency.

Seating Survey in the Garment Industry

Ill-Adjusted Chairs Cause Strain And Bad Posture in 250 Factories

By THERESA WOLFSON, EDUCATIONAL SUPERVISOR, JOINT BOARD OF SANITARY CONTROL, NEW YORK CITY.

THE survey of seating conditions in shops of the Ladies Garment Industry was undertaken by the Joint Board of Sanitary Control* for the purpose of ascertaining the problems with reference to posture of the garment worker and constructive plans which might be developed for proper seating and better posture. The survey was carried on in two hundred and fifty representative shops, both large and small, good and bad as far as sanitary conditions are concerned, and located in the new modern factory loft, as well as in the old converted three story brown house. An attempt was made to make the survey during a comparatively normal work season. There were employed in the shops under investigation at the time of the survey 2,528 machine operators, 1,774 hand finishers, and 734 pressers.

The Joint Board of Sanitary Control has been able to effect great improvements in the matter of shop sanitation, since its inception some twelve years ago. Despite the fact that the Ladies Garment Industry is large, employs thousands of workers, and involves millions of dollars, there has been almost no effort to solve the very important seating problem in the shops. This may be due to the larger economic factors affecting the industry; the fluctuating seasons, the great labor turnover, and the prevalence of the so-called fly-by-night shops. But whatever the reasons, this survey carried on by the Joint Board of Sanitary Control is an effort toward that solution. The investigation was undertaken with the cooperation of Miss Edith Hilles of the division of women in industry of the New York state department of labor.

When the average clothing factory is in need of factory chairs, an order is placed either with a small second-hand furniture dealer for kitchen chairs, or the porter is sent out to a half dozen basement stores in the vicinity, dealing in second-hand machines, pressing tables and chairs, and a heterogeneous variety of the cheapest chairs is picked up and sent to the factory.

All sorts of seating contrivances have been found in the course of this survey; ordinary crude benches, folding camp chairs, ice cream parlor chairs, straight backed dining room chairs, and ordinary kitchen chairs. Every effort to make the seat less uncomfortable has been found, boxes or pillows on chairs to make them higher or legs sawed off to make them lower.

Of the 256 shops inspected, 214 used plain kitchen chairs as the typical factory seat. In 14 shops round stools were used, and in 63 shops, benches of the crude work bench variety, fre-

Makeshift benches without backs cause round shoulders and organic weaknesses due to poor posture.

quently covered with cloth or material of some sort, were found. In two shops folding camp chairs were used and the workers struggled with a constantly collapsing seat or back.

The necessity for support of some sort for the back of the constantly sitting worker is generally recognized and yet in five shops, exclusive of the shops using benches and stools, chairs were found without backs. The worker when asked how he felt working without a back support claimed that, inasmuch as he was an operator, his position was one of constantly leaning forward and he didn't need a back support!

In the average factory the sewing machines are of a standard type run

by electricity. In 62 shops these machines were run by single motors, enabling each machine to be under the control of the operator at that machine. In 189 shops, the general motor giving power to all the machines and necessitating shafting was used, and in five shops both the single and general motors were found. The machines are usually placed on both sides of a narrow trough, approximately 16 inches wide, which is used for supplies or the support of the garment. This position of the machine necessitates machine operators facing each other, thus one row of workers usually faces the direct glare of the window light.

The machine operator was invariably found sitting at the edge of the chair, leaning forward, shoulders drooped, head bent low in an effort to follow the needle as it passed across the garment. The kitchen chair which was the most common seat found, gave practically no support to the operator's back. The back of the chair consists of five vertical rungs held together by a rounded piece at the top, and about 17 inches in height with the support coming above the shoulder blades, and so hollowed out that the small of the back received no support. The width of the seat varied from 14½ inches to 16 inches, and the depth from 15 to 16 inches. The seat was usually flat or saucer-shaped compelling a slouching position on the part of the operator when he sat back.

In fourteen shops there were found chairs and stools which were altered in height to suit the comfort of the worker. This represented a conscious attempt on the part of the worker to adjust the chair to his height. Instances of chair legs sawed off were found, several chairs were found with lead piping at the ends of the legs, to give greater height to the chair and thus prevent the worker's legs from dragging on the floor. Pillows and boxes, were also used to elevate the taller operators where the chair was too short. Every conceivable attempt to adjust the chair to the worker's height or lack of height was found. That the average worker appreciates the need of a properly adjusted seat and that he attempts to

*Pictures through courtesy of Joint Board of Sanitary Control.

secure this comfort to the best of his ability is evident.

The problem of workers engaged in the other operations of the garment trade is equally important. The finisher sitting at a small table with

This movable foot-rest was made by attaching to the table a flat board by screws to short iron pieces projecting from the ends.

her feet crossed, her back bent over the garment, her eyes close to her work, is a typical figure. The finisher used the same kitchen chair or straight backed chair that was commonly found, and the same means of adjusting these seats to the worker were also employed. The special problem of the finisher is the need for adequate foot support. In order to have a lap upon which to rest the garment, the finisher either crossed her legs or rested both feet on the ledge of the table or the rim of a finisher's basket.

The ordinary finishers' table is of the "wooden horse" variety with a small board nailed to the top of the horse, as a receptacle for pins, needles and threads, and a narrow wooden rail at the base of the stand which is ordinarily used as a support for the finisher's foot. Invariably this rail is worn to a thin strip as a result of the constant wearing away of the ledge by the foot of the worker. In only seven shops did these tables vary or was there an attempt to make the finishers' table suit the need of the finisher.

There were several constructive attempts to make the finishers' table more comfortable by the erection of spool rods on the board proper, and by attaching to the ends of the table a movable foot rest consisting of merely a flat board attached by screws to short iron pieces projecting from the ends as shown in the diagram. This is really an ideal support for the finishers' feet and tends to relieve the tedious round shouldered position. The finishers rarely get up from their seats, in fact, in only 14 shops did the operator or the finishers walk for their materials and thus relieve the strain of constant sitting. The need for adequate seating for finishers is

even more important than for other workers because their position is less varied and their posture constantly bad.

The Pressers' Problem

The third group of workers that suffer from bad posture are the pressers. The presser's occupation is such that he must stand on his feet all day long. The common ailments of most pressers, as a result of their occupation, are flat feet and varicose veins. Dr. Schereschewsky of the U. S. Public Health Service in his study in 1913 of several thousand men and women garment workers in New York City found that 55.3 per cent of the pressers had bad posture and that 72 per cent of the workers suffering from varicose veins were pressers; this notwithstanding the fact that the pressers were found to have the most robust physiques of the three types of workers. Interviews with both employers and workers relative to the possibility of sitting while at work, even on a high book-keepers' stool indicate this to be impracticable as yet. Since a variation of position is essential to elimination of fatigue, the next best thing is opportunity to sit and rest at frequent intervals during the day, giving relief to the feet and easing the strain.

The presser has another problem equally serious. The ironing tables are usually of standard height. However, attached to the ironing table is the ironing board which varies in height from 7½ inches to 10 inches above this table. The iron rest, where the iron, whether electric or gas, is placed, is anywhere from 12 to 25 inches away from the ironing board. Pressers declare it is necessary to have this distance in order to secure a "good swing" in the arm, as it comes down with the iron on the material. The weight of the iron used in the ordinary waist and dress shops or cloak and suit shops varies from 12 to 18 pounds. What is the result? A presser swings an 18 pound iron approximately 30 inches or almost a yard every time he presses—in fact the distance should be doubled for the operation is not complete until he replaces the iron on the rest.

The average presser makes about four complete circuits a minute. Therefore, he carries his iron practically 5,760 feet during the course of a work-day, allowing for interruptions of all sorts and exclusive of the actual pressing motions, which amounts to carrying an 18 pound iron a mile every day of one's working life.

The average height of a presser was found to be 5 feet, 5½ inches. The varying heights of the pressers also creates a problem; for the short presser does not reach the pressing board as easily as does the tall worker. Even here devices were found employed. Sixty-four shops were found with special tin flooring underneath the pressers' table in order to ease the strain of wooden floors against the feet. Several ways of raising the flooring in order to adjust the short workers to his table were found:—boxes, boards, planks from 1½ inches to 4 inches, varying with the height of the worker, were used.

There is little or almost no variation of position for most of the workers. Since the installation on the week work system, the work is brought to the operators, finishers, and pressers. In only 14 shops did the operators and finishers get their own materials and thus give themselves the benefit of moving their position.

Lighting for Operators

In making the study of lighting conditions, we found again the necessity of dividing the occupations into three groups and ascertaining the existing and necessary light for each of the operations of these workers. An illuminometer or foot candle meter was used to measure the actual light.

In only 145 shops of the 250 in-

An example of good seating. Adjustable chairs with proper back support have increased health and efficiency of the worker.

spected, was daylight sufficiently good to warrant the use of natural light. In 36 shops or 14 per cent of the total number, the operators were compelled to use both natural and electric light and in 38 shops or 15 per cent of the total, electric light was exclusively used.

The measurement of the amount of light for machine operators varies from 4 foot candle power daylight to 30 foot candle power; and from 4½ foot candle power, electric, to 25

foot candle power. It is impossible to present the great variations of light in different shops; it is sufficient to indicate that there still are shops where operators secure only four foot candle power of light on their work when the minimum standards set for machine work are 5 foot candle power, for light materials and 7 foot candle power, for darker materials.

In five shops there were found shadows cast upon the machine in such a way as to seriously affect the work of the operator. These shadows were the fault of poor lighting and in one instance a deep shadow was cast by a nearby partition in the loft. In 15 shops, a definite glare, because of the overhanging electric bulbs, was cast. This glare, of course, affected the eyes of the worker and hindered his clear vision.

In 22 shops, the lights were attached to the machine proper. This is an extremely bad method for the vibration of the machine invariably brings the vibration of the light, and the constant flicker produced is not conducive to good vision.

In 118 shops, finishers worked by electric light during the entire day. In 119 shops daylight was used, and in 19 shops both electric light and daylight were employed. The finishers' work is exceedingly exacting. The garment must be carefully handled and even the operator who must closely follow the machine needle

Kitchen chairs offering no support to the small of the back and of varying heights are found in many shops.

across the cloth does not require the same sort of light as does the finisher. Finishers must have a uniform light in which to work for it is essential that glares and contrasts in lighting be eliminated.

The pressers' work does not require the same intensity of light as does that of the operator or finisher. Therefore, the pressers' table is frequently placed in some corner of the shop where there is neither ventilation nor light. In 163 shops, the

presser used electric light exclusively, in only 80 shops was there sufficient daylight, and in 13 shops both electric and natural were used. These facts concerning the lighting in which workers must earn their living must be seriously weighed in the consideration of the entire lighting problem.

Certain established principles⁴ should be observed by every manufac-

ture value of good seating but the Joint Board of Sanitary Control realized that it must carry on its own experiment in New York.

Therefore, two large shops were chosen, one a cloak and suit shop the other a waist and dress shop. These shops were known as "A" shops, excellent sanitary conditions with good environment. It would have been

In addition to the bad seating shown here one row of workers must face a glare of light.

turer for his own benefits as well as that of his employees. (1) Amount of daylight admitted to interior should be as large as possible; (2) light should reach center of room; (3) distribution of light upon working planes should be as uniform as possible; (4) light should fall upon working planes from proper direction; (5) walls of room should be of such color and surfaces as to absorb but little light; (6) manufacturing and other equipment should be so disposed as to avoid casting extensive local shadows; (7) artificial illumination should be adequate for work to be illuminated; (8) uniformity of distribution of light is necessary; (9) glare effects should be eliminated; (10) troublesome shadows are to be avoided.

An Experiment in Seating

When the survey of two hundred and fifty shops was still being carried on, it became evident that though seating conditions were extremely bad nevertheless there were naught but general constructive principles to offer on the value of good seating and no concrete experiences in the clothing industry. It is true that large men's clothing factories like the Clothcrafts Shops of Cleveland and the Prinz-Biederman Ladies garment factory of the same city, have found the eco-

nomie better had we taken a small shop and contrast it with a large one, for purposes of experiment, but unfortunately this was impossible. Twelve workers were chosen in each shop, twenty-four in all, men and women engaged in different types of work, of different heights, racial, and physical characteristics, but all sufficiently intelligent to cooperate in this study. A physical examination was given to each worker by a competent orthopedic physician. The examination stressed certain points:—conditions of eyes, digestion, contour of back, shoulders, abdomen, feet, back, and hands, and other factors of the class of work performed by the worker.

Of the twenty-four workers, ten were operators, ten were finishers and four were embroiderers, doing exacting and detailed work. Six of the group were men. In shop A, the cloak and suit shop, six workers were found to have good eyesight, clear vision and comparatively little eye-strain. The other six had poor eyesight, considerable near-sightedness, and eye-strain, and were also suffering from extreme round shoulders, and bad contour of the back. This was undoubtedly the result of the need to lean forward in order to see the path of the needle.

Only two workers in this shop had perfect digestion, the rest suffered more or less chronic constipation, ag-

⁴D. H. Tuck's study of lighting in the garment industry in 1913 under U. S. Public Health Service.

gravated during the busy season of the trade when they were sitting constantly at work. The examination further revealed that seven workers suffered from a marked degree of scoliosis or lateral curvature of the spinal column, that eight workers had a condition of marked crepitus, and that six workers had pendulous abdomens. Four cases of marked flat feet and six cases of slight bow legs were found. It is true that such defects may have been a part of the worker's physique even before he started to work in the garment industry, but it is also true that the industry intensified these defects.

In testing the strength of the workers' hands the average was 70 pounds pressure, with the right hand and 60 pounds pressure with the left hand, although the lack of strength of the women finishers brought down the average considerably.

Defects Due to Seating

A similar examination was made with practically the same results in shop B, a high-class dress and waist shop employing all women ranging from 19 to 39 years of age, the majority of them Italian. Three of the four embroiderers had good eyesight, clear vision, but had been working at embroidery for a comparatively short period, the fourth having extremely bad vision had been doing this sort of work for several years. Of the remaining eight workers, three had bad eyesight with marked eyestrain.

The posture examination revealed four instances of marked curvature of the spine; seven cases of round shoulders; and ten cases of flat feet. The latter condition may have been aggravated by the prevailing use of extremely high-heel shoes. The strength of the hands averaged 50 pounds right, and 45 pounds left. All the workers in both shops suffered keen fatigue at the end of the work-day and had little spirit left to do anything else. Fourteen out of twenty-four workers suffered chronic constipation and were alleviated only when they were out of work and could walk around or sit in the parks.

After the physical examination, each worker was given a special chair to be used at work for a period of four months. These chairs were loaned by three different chair companies interested in working out a properly adjusted factory chair for the garment trade.

It was the plan of the study, to ascertain the extent of production as affected by the elimination of fatigue when good chairs are used, but inas-

much as the shops were of the better type where quality rather than quantity was the keynote, we were unable to secure statistics of production. In fact, all that was available was the testimony of the foreman who spoke for the employers, and the statements of the workers who were intensely interested in the experiment.

Bi-weekly visits were made to the factories at different hours of the day in order to ascertain just how much fatigue the worker had in the morning, after lunch, at three o'clock. During the first week the responses varied: "I'm not used to the chair," or "The chair seems queer," or "I feel fine in this chair," or to the response of one stout woman finisher who said, "This chair seems to make me less tired, my shoulders don't hurt so much, my eyes don't feel so tired—and my head doesn't feel so heavy!" From week to week the comments changed and valuable criticism of the chairs used were given by the workers. As soon as the workers became conscious of the fact that there was a seating problem they were the most valuable aids in eliminating certain features of the chairs which inconvenienced the operators or the finisher.

Certain principles were evolved to solve the seating question:—(1) The seat should be about 16 inches wide, slightly saddle-shaped to fit the back and seat of the worker; (2) front edge of seat should not cut into knees and thereby impair circulation; it should be rounded and not sharp; (3) chair must be adjustable to the height of the worker; (4) back support must be slightly curved and give support to back of worker, preferably a little below the shoulder; it should be adjustable; (5) chair must be comparatively light so that it can easily be moved; (6) chair should have firm base and not tip backward as worker leans back; (7) there should be no bars at the base of the chair to cut the operators' feet or ankles as he leans forward.

At the end of the second month an attempt was made to exchange the chairs and in shop B this was done. In shop A the workers wanted to keep their chairs, they had become so accustomed to them they did not want to change. This, of course does not mean that there were no criticisms of the chairs used. They were by no means perfect, but they were so far superior to the old type kitchen-chair that criticism merely improves them still further.

After a period of four months, the workers were examined. It is true

miracles were not performed, but the consensus of opinion of the workers was that they felt better, certainly less tired, at the end of the day than when they used the old kitchen-chair, and in the case of four workers there was a marked improvement in their general posture and an elimination of round shoulders.

This experiment carried on in an industry employing over 150,000 men and women workers is an index of what can be done with the cooperation of the manufacturers and the workers for the elimination of the evils of defective seating and resultant bad posture.

Science has established certain facts: first, that bad seating causes fatigue, secondly, that fatigue is responsible for bad posture, thirdly, that bad posture leads to deformities least of which are round shoulders, sunken chest, deviation of the spine. The economics of production has also established certain facts, the most pertinent being that tired workers retard production, and that properly adjusted seats and good lighting eliminate fatigue, and thereby increase production.

The Joint Board of Sanitary Control presents this study as the first step in the solution of an important problem in an industry which is probably one of the least standardized and least amenable to the so-called efficiency standards, and yet has a strong human sympathy for improvements indicated by progress.

New York's School Survey

Following its child health survey, the child welfare committee of the New York State League of Women Voters recommends a consolidation of rural school districts, more adequate building programs, enforcement of the state medical inspection law with regard for the spirit rather than mere compliance with form, provision by local communities of an adequate number of school nurses. It urges adoption of the county as the unit of administration, and taxation as the most promising means of filling those needs in rural schools. Of the 11,824 schools in the state, nearly nine-tenths are rural schools. The survey showed 8,600 one room schools and an attendance of less than ten pupils in something more than three thousand rural schools, which formed the basis of this study. More than half of the rural school buildings were over fifty years old and at least 13 per cent of the school plants were built more than seventy-five years ago.

The Equipment of a First Aid Room*

THE importance of having first-aid outfits for the preliminary treatment of injured persons in our manufacturing plants was early recognized, and as our industries expanded and accidents increased in number, the need for such outfits became more acute and more obvious, and in large plants it has been found to be desirable to set aside special and more or less elaborately equipped quarters for treating injured persons. First-aid rooms, in former days, were usually put in charge of employees who were supposed to be qualified to render first-aid service although untrained in medical science in its broader aspects; but it has now become common practice, in plants of sufficient size to justify the expense to employ a specially trained nurse for administering emergency treatments.

The first-aid departments of manufacturing plants have in fact developed quite extensively in various directions, and the treatment ranges all the way from the giving of first aid in the case of injuries, to the maintenance of small but high-grade hospitals.

The medical department in any plant should be such as to invite visits from the employees, and medical treatment should be available to them during all working hours. Courtesy, sympathy, kindness, and a manifest desire to render real service, should characterize the treatment in every case, whether the patient be a company officer or an unskilled workman. All are equally deserving of attention, time, and help, and when an employee from the lower strata finds that he receives the same treatment that is given to his foreman or superintendent, his loyalty to the company is greatly promoted.

"First aid" appears to be all the medical aid that is required to meet the needs of the small plant whose employees number from one to three hundred. To insure privacy both to the injured and to the person giving the emergency treatment it is highly important to set aside a special room for the purpose of administering first aid, and this room should be placed in charge of someone who has received instruction in first-aid work from a competent physician or trained nurse. The first-aid room should be light and airy, and should include among its furnishings two or more chairs, a

small table, and washing facilities consisting of hot and cold water, soap, and a supply of clean towels. In plants occupying more than one building or floor, a stretcher should also be provided.

The contents of the first-aid kit should be substantially as follows: Instruments—1 pair of scissors, thumb forceps, tourniquet, graduated medicine glass; drugs—2 ounces of aromatic spirits of ammonia, 2 ounces of 4 per cent boric acid solution, 2 ounces of alcoholic iodine solution, half strength, 2 three-ounce collapsible tubes of vaselin, containing 3 per cent of bicarbonate of soda (for burns), 2 ounces of castor oil (for eye injuries); dressings—1 dozen sterile gauze bandages (assorted sizes), 1 spool of adhesive plaster, 3 packages of absorbent cotton ($\frac{1}{2}$ ounce each), 3 packages of sterilized gauze (1 yard each), splints of assorted sizes, wooden applicators wound with cotton, wooden tongue depressors.

The first-aid room serves admirably as a place where an employee can seek rest and relief in case of illness as well as treatment in case of accident. In the larger plants one or more cots may also be provided, so that patients may lie down for a while, and the medical equipment of such rooms often includes many other simple remedies, in addition to those listed above. In plants in which the work is

unusually strenuous or hazardous, or in which women are extensively employed, it is desirable to maintain special rest rooms.

In plants employing more than three hundred persons it may be desirable to enlarge the facilities for rendering aid to the injured and to establish a dispensary. The dispensary occupies a position intermediate between a first-aid room and a hospital, because it receives cases of illness as well as of injury. It may be regarded as a first-aid department with enlarged activities, but as its functions are broader, and its management differs from that of a true first-aid room, it is desirable to call it by a different name.

A dispensary should always be in charge of a skilled nurse who is qualified to treat the sick as well as the injured, and to guard against the hazards of industrial poisoning. This nurse should devote his or her entire time to attendance at the dispensary during working hours. The dispensary should be housed in a special room or building set apart from the workrooms, and the equipment should be such as to allow the nurse in charge to work efficiently without being hampered by lack of proper supplies or facilities. Running hot and cold water should be available and a complete first-aid kit supplied. One or more stretchers should be kept ready for emergency use, and a few of the more

A well-equipped first-aid room

*Printed by courtesy of The Travelers Insurance Company from The Travelers Standard, December, 1922.

simple remedies for common ailments should be provided.

The dispensary idea can be enlarged upon as the needs of the plan require. In some instances an industrial physician is employed to devote part of his time to work in the dispensary, but whether a skilled nurse or a physician is employed will depend upon the nature and extent of the medical aid required.

When the medical needs of a plant are such that the services of a physician are necessary, an emergency hospital is usually established, and equipped with an operating table, couch and chairs, table for dressings, sterilizers for instruments and dressings, and a supply of dressings and splints and the more common drugs and medicines. When an emergency hospital is provided, a graduate nurse devotes all of his or her time to work at the plant during working hours, and in addition the plant management employs a physician who visits the plant to supervise the medical work at least twice each week. At other times during the working hours of the plant he should be available to call.

A fully organized hospital is needed only for the continuous care of the more serious injuries and illnesses, and in most industries such cases are few in number. Rapid growth and expansion are increasing the need for equipment of this sort, however, and the view of what constitutes a hospital case is continually enlarging, so that minor injuries are being included in this class more and more. The hospital is the only place where a physician can be sure that his directions will be carried out correctly, and continuous clinical observation for the first few days often prevents the development of serious consequences from small injuries and seemingly minor illness. If a good general hospital is within easy reach of the plant, a special industrial hospital may not be necessary, even in a large plant having thousands of employees. But if the work in the plant involves processes of an unusual nature, or if the exposure is largely of one particular kind, the plant hospital may be able to render much better service than a general hospital, because the physicians or surgeons who are in charge will have an excellent opportunity to specialize in the direction of the particular accidents and ailments that the plant produces. This is obviously true, for example, in connection with industrial poisoning due to the absorption of substances that are not used in other plants in the neighborhood; and it is manifest that many

other examples could be given.

It is not possible to give general advice with regard to the need for a special, fully-equipped plant hospital; but in any given case it should be easy to determine whether the installation of such an institution is advisable or not.

In a large plant it may be advisable to have several nurses on the medical staff in addition to an industrial physician. If a hospital is included, nurses will manifestly be needed; but they may be equally necessary even if the plant facilities do not extend beyond a dispensary, and a small plant often finds one trained nurse to be absolutely essential. Some plants employ visiting nurses, who go to the homes of sick and injured employees and assist, in various ways, in keeping the stricken household in running order. This service is a fine thing from a humanitarian standpoint, and if the employer desires to offer it he will certainly merit and doubtless receive the thanks of his employees.

In a plant employing a considerable number of men or women, it is distinctly advantageous to enlist the services of a good dentist, for prophylactic work, because the teeth are known to be responsible for a considerable number of diseases. Dental examinations may be specially important in industries handling chemicals of certain kinds. To examine the employees, a dentist need not spend more than one day a week in a plant employing 250 men, and the cost of such examinations should be borne by the employer. Where a dentist is employed for a greater time than this, and where he does more than make diagnoses and give simple treatments, a small charge is usually made to the employee for the work done.

Employees should be encouraged to consult the plant physician, or the nurse in charge of the dispensary, and they should be impressed with the fact that the medical department is there for their use and benefit. They should also be taught that the prompt treatment of a small ailment will often forestall and prevent more serious trouble.

In many of our larger plants employees are subjected to a reasonable physical examination for the purpose of determining their general physical condition, and to prevent the assignment of a man to an employment that would jeopardize his life and health. It is manifest, for example, that a man who has a hernia should not be set at work where he will have to do heavy lifting, where extra work will be thrown upon the heart, nor should

a man who is subject to epilepsy be allowed to engage in work where a sudden seizure would place him in imminent danger. Such men should be employed at tasks appropriate to their condition. The men have everything to gain from examinations of this kind, and we recall a recent case in which a large body of men were so thoroughly impressed with the wisdom of the plan that they requested their employers to give these same examinations, at reasonable intervals, to the men already employed. It is wise to provide the needful facilities for such examinations.

Safety on Walkway Surfaces

Fatalities due to falls constitute about one-fifth of the total number of deaths from all causes. The safety committee of the National Electric Light Association reports that among sixty-nine companies in twenty-two different states, accidents due to falls resulted in a greater amount of lost time than those due to any other cause.

The American Engineering Standards Committee therefore called February 14 a conference of forty trade associations, technical societies, and safety organizations for the purpose of determining whether it is desirable to have nationally uniform specifications relating to walkway surfaces, and, if so the several types of surfaces which should be applicable to (1) elevator floors, elevator landings, hall floors, ramps, runway floors, and stair treads; (2) apartment houses, factories, office buildings, hospitals, hotels, railway cars, railway stations, schools, theaters, and other places of public assembly.

The performance characteristics of materials would need to be determined as to frictional resistance and durability. Other qualities would require special study, as would the correlation of safety provisions now operating or in process of formulation. Accidents, never isolated and unrelated happenings, states the committee, may thus be made the subject of scientific study and be brought under definite control.

The centenary of Pasteur will be celebrated in Strasbourg by an international exposition from June 1 to October 15, 1923, which will cover all branches of hygiene, industry, housing, nutrition, and agriculture. The exposition is designed to show to the public the influence of Pasteur's work on different phases of human activity.

Incineration in Institutional and Industrial Buildings

Much technical work is extant on the subject of the collection and disposal of municipal refuse, but comparatively little can be found on the methods and apparatus used by the great public institutions, railroad terminals, markets, hospitals, private industrial establishments, and many other places where incineration is employed as a means of waste disposal. Yet, taken altogether, the number of these smaller installations is far greater than that of the municipal disposal plants, and in the aggregate the daily quantities dealt with will nearly equal the amounts handled by the civic plants. The usefulness of these minor installations is established beyond question. The uses of private incineration plants for the disposal of worthless matter produced in industrial enterprises is discussed by William F. Morse in a recent issue of *Municipal and County Engineering*.

For the disposal of the waste of market houses, he says, there is no method so satisfactory as incineration on the premises. Given a market containing from one hundred to 150 stalls, handling every variety of food products, there is a daily accumulation of material of from ten to fifteen cubic yards, weighing from three to five tons, according to seasonal conditions. If it is undertaken to haul this to a dump, the daily cost of transportation is a considerable added expense. It is economically disposed of by means of incineration and in strict accordance with sanitary principles, and without nuisance to persons or property.

The apparatus for incineration is not complex in design. It can be built from detailed working drawings by a competent bricklayer who can read plans and follow clearly printed instructions.

According to Mr. Morse:

The floor space for the incinerator must not be less than 8 ft. by 6 ft., with room on one side for stoking and for removal of ashes. . . . The usual location is on the basement of cellar floor, and the incinerator is connected with the main chimney of the heating plant, or with the boiler smoke flue. If the location is outside the building, a special steel stack or brick chimney, rising above the top of the market building, is provided.

The fire-box, floored with heavy cast-iron grates, is charged from the main floor of the building through a chute covered by a fire-clay slab enclosed in a cast-iron rotating frame. The interior walls, roof, and connecting flue are of the best quality of fire brick and the whole structure is

stayed by vertical and horizontal steel beams and angles. No iron is exposed to the flame except the face of the cast iron lining to the stoking door. The consuming heat may be raised to the highest temperature and maintained indefinitely without injury to the furnace.

The practical results of such construction is the destruction of all market waste without the use of fuel other than the material burned, the intermittent labor of one man only. The disposal of worthless matter is thus accomplished in a sanitary way, and at an extremely low cost.

The great Hudson terminal building is mentioned as utilizing an incinerator with a capacity of ten tons to receive the daily garbage, combustible refuse, floor sweepings from rooms and corridors cleaned by the vacuum process, and the refuse from the railway used by five thousand daily travelers. In this way the enormous volume of waste is disposed from the multitude of industrial plants housed in the Bush Terminal building at South Brooklyn, N. Y. The same method is in wide use in army posts and labor camps.

Physicians in Industry

AMONG the subjects discussed at the thirty-sixth meeting of the Conference Board of Physicians in Industry, held January 20, 1923, was that of industrial medical records and x-ray examinations. In the experience of the members, in many cases extending over a period of ten or twelve years, it had been found that records kept by the medical departments were of much value to the organization. An instance of the value of these records was cited in their use for reemployment of workers who had been dropped during the industrial depression. In many cases the records showed the defects of workers without the necessity of a second physical examination.

Another use of these records was shown in the checking up of the physical condition of those workers who had been absent on account of illness. In one instance a close study had been made of one hundred workers who had been sent away for the treatment of tuberculosis. Their attendance record after recovery and return to work was much better than that of a similar group of workers not so affected. This experience shows that the tuberculous workers had learned how to take care of their health while the supposedly well person paid little attention to this important matter.

Another instance was cited where the investigation of the records of a group of defective workers who had been taken on during the shortage of labor following the war showed that a large number of such workers had been retained during the industrial depression. Here again experience has shown that the defective worker when properly placed in a suitable position was a more reliable and steady worker than a normal person who has

less trouble in securing employment.

The value of dispensary records was shown in another instance where such records had proved a marked reduction in the number of eye injuries occurring in certain departments presenting eye hazards where the wearing of goggles was compulsory.

A report was submitted upon the x-ray examination of the chests of over three thousand employees in one factory. By refinements of technic, it had been possible to make these exposures at the rate of about one per minute. A specially devised caliper was shown for measuring the depth of the chest, thus enabling a more accurate exposure. The result of this study showed that 3.7 per cent of those examined had positive or suspicious symptoms of pulmonary tuberculosis, 3.2 per cent showed abnormalities of the heart or aortic arch and 0.8 per cent showed miscellaneous chest abnormalities; 7.7 per cent showed chest abnormality.

A Correction

On page 617 of the October, 1922, issue of THE NATION'S HEALTH appears an article on drug misconceptions as applied to surgery in which reference is made to certain deleterious effects which follow the use of miscellaneously compounded carbolated ointments. The use of the term "vaselin" in this article was inadvertent and had no reference either specific or implied, to "Vaseline," Carbolated Petrolatum Jelly, the product of the Chesebrough Manufacturing Company. Although "vaselin" is given in medical dictionaries and has been used in medical literature as a common noun, "Vaseline" is a trade name and was improperly applied by the author of the article to which reference is made in this correction.

Abnormal Air Pressures

MUCH has been heard in recent years of the great danger and high accident rate wherever men are engaged in tunnel construction under the abnormal air pressures necessary in driving through materials under hydraulic pressure. In most cases greater attention has been paid to the prevalence of caisson disease than to the usual class of accidents which occur in the building of tunnels under normal air pressure. Robert W. Jones, writing in *Compressed Air Magazine* discusses the subject and gives the results of recent observations that have a direct bearing upon the hygiene involved. On the part of engineers there seems to be a general feeling, states Mr. Jones, that if the construction is being carried on under the protection of a rock face conditions are safer than when the tunnel is being driven through soft material. This is seldom the case.

Comparison is drawn between accidents that actually occur under abnormal and normal air conditions. The following general figures are given from the accident book of a corporation recently engaged in tunnel construction under conditions remarkable for the high standard of work and the high air pressures. Every man who was injured, no matter how slightly, was expected to report to the doctor, and a complete record of all accidents was kept. The record as given covers a period of 170 days, from January to June, during which period the air pressure varied from twenty-one pounds to forty-seven pounds per square inch.

Nature of accident	Hospital Cases	Deaths
Powder fumes	1	..
Electric burns	2	..
Pinched by tools	2	..
Fights	3	..
Failure of tools	9	1
Nail punctures	13	..
Miscellaneous	14	3
Eye injuries	16	2
Falls	18	6
Falling rock	21	4
Falling tools	29	3
Transportation	35	2
Caisson disease	68	1

Mr. Jones' discussion of these accidents follows: The percentage of accidents resulting in hospital cases was 8.6 for caisson disease and 13.5 for all other injuries. This is considered typical of what occurs in tunnel construction under high pressures. The law and the codes relative to air work are as complete as it is possible to make them and are rigidly enforced. The results are shown in the low rate of caisson disease hospital cases. The company has shown in the last two years only one death caused by working under high pressure. . . . The cases under miscellaneous were almost entirely due to

changes in temperature, resulting in "colds" which are properly classed as accidents. The accidents listed are not excessive.

In ordinary tunneling operations under normal air, there would not be over three changes of shift in twenty-four hours, but in the case of work under higher pressure, when the accidents were listed, the length of shifts varied from eight hours per twenty-four to ninety minutes per twenty-four hours, with the ninety minute period divided into two shifts of forty-five minutes each, and with a five hour interval between shifts.

Standards Gain in Legislation for Injured Workers

Recent legislation in extending workmen's compensation laws has been made to cover occupational diseases, to reduce waiting periods before payment begins, to raise compensation allowed, to remove arbitrary limitations on medical care, and to provide at actual cost through state funds insurance protection against industrial accidents, according to the eighth annual edition of "Standards for Workmen's Compensation Laws," just issued by the American Association for Labor Legislation. Forty-two states have adopted compensation laws, and, while the health protection of the workmen is in many states inadequate, on the whole the report shows a broader treatment of the whole subject and better basic studies.

Disease, Not Accident, the Chief Cause of Disability

Some significant facts are brought out by the published analysis recently made of the total and permanent disability claims paid over the fourteen year period just past by the Pacific Mutual Insurance Company. The great increase in the number of claims under this clause is shown by the following tabulation:

PERMANENT TOTAL DISABILITY CLAIMS PAID.

Year	No.	Value
1908	2	\$ 2,533
1909	4	5,744
1910	4	5,292
1911	6	8,657
1912	5	8,787
1913	10	12,522
1914	7	10,265
1915	12	13,907
1916	9	10,185
1917	12	35,866
1918	6	19,551
1919	6	35,825
1920	45	102,580
1921	59	176,910
1922*	73	253,224

*1922 through October only.

On the part of public health workers great interest attaches to the analysis made of the causes of the

permanent and total disabilities on which annuities were awarded.

Of all causes the great white plague, tuberculosis, heads the list. Forty per cent of all the company's permanent total disability claims have as their cause tuberculosis. Insanity comes next, being the cause of about 25 per cent of the claims allowed; while paralysis comes third. One would very naturally assume that accident would be the chief cause of permanent total disability. In this company's experience, however, this is not the fact. Disease, far more frequently than accident, produces permanent total disability, says the report.

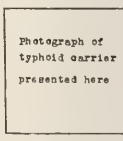

Tests of Dust Respirators

Dust respirators for protecting workmen from inhaling injurious dusts in mines or other dusty places are undergoing tests at the Pittsburgh, Pa., experiment station of the Bureau of Mines to determine their relative merits. Silica rock dust suspended in air and tobacco smoke are being used as test mediums. Various fabrics have been compared for their filtering qualities, the best so far having been cotton flannel and dense wool felt. Filter paper of close texture also tested high against very fine particles. A dust respirator of superior efficiency and comfortable to wear may be designed from results of this investigation.

Typhoid Carrier Circular

TYPHOID-CARRIER

THIS MAN IS NOT TO BE EMPLOYED AT ANY DAIRY OR OTHER FOOD HANDLING ESTABLISHMENT

Photograph of
typhoid carrier
presented here

Color: White Age: 19 Years Height: 5 feet 11 inches	(Normal) Weight: 175 lbs Build: Robust Eyes: Deep brown Hair: Black, gray streaked	Complexion: ruddy Moustache: brown Beard: no teeth Occupation: laborer High-receding forehead
---	---	---

This man has been released from custody on the agreement that he will not work at a dairy or other food establishment. He has made a practice of getting employment at dairies where he caused the following cases and deaths from Typhoid Fever:

72 known cases and 3 deaths at an orphan asylum in Morris County from June to September, 1921

33 known cases and 3 deaths at Newark from September to December, 1922, spread by milk from dairy employing him

HEALTH DEPARTMENT.
Newark, N. J.

January 1, 1923

Circular distributed by the Newark, N. J., department of health to dairy and food handling establishments supplying the city with milk and other food. This carrier had already been responsible for two outbreaks of typhoid. He was released from custody upon his promise to refrain from handling food and to permit this description to be broadcasted by the health department.

New Federal Department

THE creation of a government department dealing with problems of education, health, and welfare, headed by a secretary in the president's cabinet will be asked soon by the joint committee on reorganization of the government appointed from both houses of Congress two years ago.

At the request of President Harding, a meeting of the executive committee of the Conference of State and Provincial Health Authorities was held in Washington, January 15 to 16, at which time Brigadier-General C. E. Sawyer explained to the executive committee the contemplated reorganization. The committee in charge of plans believes that an assistant secretary should have jurisdiction over the director generals of the four subdivisions to be called the Bureau of Veterans, Bureau of Health, Bureau of Social Service, and Bureau of Education. The Bureau of Health would assume the duties now carried on by the forty medical divisions of the government engaged in public health work.

General Sawyer said, in his address to the conference, "We are assured by all concerned in the reorganization plans of the government that they are agreeable to the carrying out of an idea which will promote the interests of medicine and make it possible to develop a public health system in the United States superior to any in the world."

Signers of the resolution favoring the creation of the new department were Gen. M. W. Ireland, Surgeon General of the Army; Gen. Hugh S. Cumming, Surgeon General of the United States Public Health Service; Admiral E. L. Stitt, Surgeon General of the Navy; Lieut. Com. J. T. Boone, Medical Corps, United States Navy; Dr. A. T. McCormack, state health officer of Kentucky; Dr. R. M. Olin, state commissioner of health of Michigan; Dr. James A. Hayne, state health officer of South Carolina; Dr. Ennion G. Williams, state health commissioner of Virginia; Dr. C. W. Garrison, state health officer of Arkansas; Dr. A. J. Chesley, secretary of the state board of health of Minnesota; Dr. W. A. Pearson, dean of the Hahnemann Medical College and Hospital of Philadelphia; Dr. A. W. Belting, president, Eastern Homeopathic Medical Association; Dr. Gilbert Fitzpatrick, chairman, American Institute of Homeopathy; Dr. William A. Woodward, representing the Amer-

ican Medical Association; Col. W. O. Owen of Washington, D. C., and Dr. Claude A. Burrett of Rochester, N. Y.

Signers requested that the name of the proposed department be the Department of Education, Health and Welfare instead of the Department of Public Welfare.

Pit-Head Baths in Colliery Areas

Bathing facilities for workers in coal mines, quite generally in the United States, compulsory in Germany, and in wide use in France and Belgium, have not been required in England. Instead of the ideal condition, therefore, which enables the miner to go to his work in ordinary clothes like other men, to change and store those clothes safely after putting on pit clothes and clogs, and after his work is done, to remove sweat and coal-dust and return home clean, is in decided contrast to the condition described by E. Colston Williams, before the recent meeting of the Society of Medical Officers of Health in London. The picture of the miner to whom bathing facilities are not available given by the *Lancet* as follows:

The miner may live some miles from his mine, to which he travels by train, having a long walk at each end of his railway journey. Arriving perhaps wet through, and it may be exposed to wind and rain while waiting for his cage, he works underground in draughty, damp conditions, aggravated by the sweat from his labor. The sudden transition of temperature when he goes again to the surface; the uncomfortable trip home, the bath at home, often taken in the kitchen in the presence of the women-folk; the pollution of the home atmosphere by the odor of coal dust on drying clothes; the labor of the women in preparing the bath and cleaning up; the incidental danger of the system through scalding accidents to the miners' children; not to mention the psychological effect on the miner of having to travel in public conveyances in blackened and dirty clothes are extremely disagreeable.

The compulsory provision of pit-head baths in colliery areas recommended by the Royal Commission on Mines in 1906-9 was objected to by the owners unless the use of the facilities by the workers was compulsory. The Miners' Federation of Great Britain advocated compulsion on the miner, but they were not backed by the men. In the Coal Mines Act of 1911, therefore, the position is taken that a majority of two-thirds of the workmen is to be obtained by ballot

before the owner is required to provide bathing and clothes-drying facilities at the mine, and that the workmen have to undertake to pay half the cost, the charge not to exceed 3 pence per head per week.

This provision is impracticable, because the maximum charge on the men would not meet half the cost; but by 1920 there were, according to Chappell, seven installations in Lancashire, Yorkshire, Scotland, and Wales. Dr. Williams gives the following description of the installation in Glamorgan:

These baths were provided by the generosity of certain shareholders in the Ocean Colliery Company at a cost of eight thousand pounds and were opened in 1916. They include an ambulance station and general office. There is a large central dressing room adjoining fifty-four bath cubicles in a separated corridor which affords privacy without doors. There are special baths for boys and officials.

The clothes are hung on endless chain suspenders running from the roof to the floor, fitted with hooks, and near the floor level are radiators for drying and airing. Each miner has his own numbered chain which he can padlock to prevent tampering with his clothes. Hot and cold water is laid on to a spray in each cubicle, controlled by the bather. Upstairs is a drying room for wet clothes.

Each man takes about seven minutes for his bath, and the seventy sprays serve 420 men an hour. In the ninety minutes which it takes to bring up a shift from the mine, 630 can be put through without waiting. The men provide their own soap and towels, and pay sixpence a week, which covers only part of the expense. There are 2,200 men employed at the mine and from 60 to 70 per cent use the baths. The management is by a joint committee of equal numbers of representatives of the men and the owners.

There is much apathy among the miners, for a proposition for further installation in the next valley was turned down by the men. The Miners' Federation approves the principle, but holds that the cost should be a charge on the industry to be borne by the owners—a change that would involve fresh legislation.

As a result of the findings of the Sankey Commission of 1920 there is a Miners' Welfare Fund to improve social well being, recreation, and general conditions of life among the miners, and to promote research and mining education. It is supported by a levy of a penny on each ton of coal raised. The fund is administered by a Miners' Welfare Committee consisting of five members appointed by the Board of Trade, including a medical member (Dr. E. L. Collis). The committee is assisted by three assessors appointed by the Ministry of Health, the Board of Education, and the Scottish Office. Applications on the fund have been made, up to date, as follows: For recreation grounds, parks,

etc., 108 aggregating 255,000 pounds; for workmen's institutes, 55, aggregating 139,000 pounds; other claims, 13, amounting to 9,500 pounds.

Dr. Williams suggests that the Fund can do much for improving ambulance service and first aid, for establishing massage centers for joint injuries and fractures. The supply of drinking water to underground workers is mentioned rather as a matter for the Factory Acts.

Lead Poisoning in the Pottery Industry

An increase in the number of cases of lead poisoning reported in the pottery industries of England is noted, though a particularly stringent code of regulation applies to potteries for its prevention. Thirteen fatal cases were reported in 1920, 11 in 1921, as compared with 6 in 1914. The average of reported cases was 76 for 1909 to 1911. There were 21 cases in 1919, and 24 in 1920.

The continued occurrence of fatal cases is of special interest, and the *Lancet* reports on the length of employment of these workers before death. Only one of the fatal cases commenced work after the present regulations came into force, and in this case some doubt existed whether the nephritis which caused death was of industrial origin. The average length of employment of nine victims in the industry was 34 years. A second case had been employed in another industry for eight years before death.

These cases show that for a chronic poison like lead many years must necessarily elapse before the benefit of improved conditions can find expression in mortality data. Since the paramount influence in causing lead poisoning has been definitely determined as the inhalation of lead dust, marked reduction is possible through hygienic measures of protection, but as long as lead is used in industries, danger must exist.

Hygiene of Laundry Work Studied in England

Too great overheating of the air has been found the greatest health hazard in the British laundry trade, according to investigation by Miss May Smith for the Industrial Fatigue Research Board, report of which appears in *The Lancet*. This overheating appears to be the laundries' most insistent problem.

The study also revealed the need for

seats during temporary lulls in work and the mistake of allowing girls who are on their feet all day to wear narrow-toed, high-heeled shoes instead of broad low heeled boots. Change of occupation to prevent long repetition of some wearisome movement, such as back bending, and to prevent monotonous fatigue was recommended. Unnecessary irritation by defective organization and machinery poorly adapted to the worker were also causes of fatigue which might be eliminated.

British laundries were found to be housed in a wide variety of buildings—from specially designed well-equipped factories to those housed in buildings little better than stables.

Study of workers at work showed that the time interval in performing given tasks was found to be longer during a ten hour than during a nine hour day, and lengthened with the afternoon. No evidence was found, however, that a reduction of hours increased total output. The psychological "dotting" test showed that work improved or deteriorated with such things as interesting or monotonous work, healthy vitality or presence of sick headaches. Errors were found to be from 10 to 20 per cent greater in the afternoon than in the morning, larger in later hours of afternoon than in earlier, smallest on Tuesdays and Wednesdays, and largest on Thursdays and Fridays.

Child Labor Highest in Cotton Mill Cities

According to figures recently given out by the National Child Labor Committee, the cities having the greatest percentage of child labor are also the cities having the highest percentage of cotton manufacture, and they are all located in Massachusetts and Rhode Island. The *New York Times* gives the following summary of the situation from a speech recently made by Atherton Brownell, member of the National Committee:

The city having the undesirable distinction of being the worst in the country with regard to the employment of children is Woonsocket, R. I., closely followed by Fall River, Mass. Then comes Pawtucket, R. I., New Bedford and Lawrence, Mass. All of these cities have more than 17 per cent in child labor. Compared with this the large cities which have no such manufactures range from 7.2 per cent in Chicago down to less than 3 per cent in Cleveland. Boston shows 6.4 per cent.

Mr. Brownell declared that he was able, through the courtesy of the United States Census Bureau, to

make public for the first time definite figures regarding the relations between cotton manufacturing and child labor.

I am now able to say on the authority of the census bureau that of the 2,133 children of New Bedford from 10 to 15 years of age, inclusive, 1,296 were employed in the cotton mills in 1920, he said. In Fall River out of a total of 2,660 children employed in all activities, 1,775 were at work in cotton mills.

Industrial Commission of Colorado Reports

The compensation department of the state of Colorado is responsible for all the details of administering the provisions of the workmen's compensation act, the industrial relations act, the state compensation insurance fund, and the Colorado minimum wage law. The sixth report just issued covers not only a summary of the work during the year from December 1, 1921 to December 1, 1922, but presents statistical tables which set forth in form comparable year by year the nature and amounts of claims and awards.

There have been 96,782 reports of accidents filed since the inception of the law up to and including November 30, 1922; 24,663 claims for compensation have been filed within the same period of time. This makes an average of 12,500 accidents per year, and approximately 3,400 claims per year. The number of accidents in 1922 indicates a decrease from 13,904 to 12,854; 4,201 claims were made for compensation in 1922 as against 4,025 such claims in 1921; 1,316 referee's awards were entered in 1921, as compared with 1,143 such awards in 1921; 167 petitions for review were filed in 1922, as against 138 for 1921. The coal industry was responsible for 46.45 per cent of the fatal claims; the metal industries for 12.25 per cent; and miscellaneous industries (all others) for 41.29 per cent. Of the non-fatal claims the coal industry was responsible for 24.39 per cent; the metal industries for 11.37 per cent; and all other industries for 64.24 per cent. The average number of weeks of disability recorded was 12.46.

The chief handicaps of the administration of the law in Colorado is reported to be the insufficient appropriation for its administration. Remedies for this were sought through the 1922 legislature by providing for simplification of compensation procedure and for flexibility of administration. These measures were defeated. The disputed points having been since set-

tled by supreme court decision, it is expected the situation will be clarified at an early date. The administration of the state insurance fund is reported as highly satisfactory.

While the report consists mainly of tabulations of the decisions of the industrial commission, interesting details of medical plans and benefit disbursements are given.

Work Conditions Affecting Linen Weavers

A study of efficiency in fine linen weaving constitutes the basis of a recent report by H. C. Weston of the Industrial Fatigue Research Board. Attention is particularly directed to atmospheric conditions with regard to temperature and humidity. In weaving, the loom rather than the weaver determines the pace, which is only limited by the tendency of threads to break, when the weaver has to tie up the broken ends. Less difficulty of this kind is encountered when the work is done in a warm, humid atmosphere. The activities of the weavers, naturally, are adversely affected by the conditions which are most favorable to the tenacity of the thread. The economic limit for linen weaving is reached at a wet bulb of 73 degrees F. Above and below this point productivity falls off.

Lighting and hours of work were likewise investigated. Artificial light, even though the illumination was good, reduced the output 11 per cent as compared with work under daylight conditions. The optimum hours of work were not determined. The report is one of a series which will take up various matters pertaining to hygiene of the textile industries.

Steel Corporation Saves 35,313 from Accidents

The United States Steel Corporation has spent more than one hundred and eight million dollars for safety, sanitation, welfare, and pensions during the last ten years, and considers it a good investment. The sum of something more than nine million dollars charged to accident prevention has, according to a statement just issued by Charles L. Close, manager of the bureau of safety, sanitation, and welfare, saved 35,313 men from death or serious injury since 1904.

A chart of the year by year trend of the accident rate per one thousand employees shows that, taking the plants of all the subsidiary companies as a whole, the rate for serious acci-

dents has decreased 56.13 per cent since 1906, when the bureau of safety, sanitation, and welfare was organized. Since 1912 the rate for all accidents has been decreased 71.41 per cent. The latter reduction in the accident rate, the report says, means that 193,232 men have been saved from injury since 1912.

During the early part of last year, a total of 136 plants, mines, and other properties with an average employment of 55,639 men, went through an entire month without a single disabling accident, and some of these plants were operated from two to six months without a single injury to a workman.

The bulletin quotes the following from Judge Gary's original instructions to the subsidiary companies regarding the safety of employees.

The United States Steel corporation expects its subsidiary companies to make every effort practicable to prevent injury to employees. Much can be done by designing new construction and machinery with all practicable safeguards. Expenditures necessary for such improvements will be authorized.

Women as Insurance Risks

Fewer women than men apply for insurance, states Dr. W. W. Beckett, medical director Pacific Mutual Life Insurance Company, and there is greater percentage of border-line cases and greater adverse selection against the insurance company. Examinations are usually more superficially made in the case of women than in men.

These facts are to be considered in conclusions drawn from a statistical study of the women written by the company in question, and published in the current issue of *Insurance News*.

In women under thirty-five the death rate is higher during the first five years the policy is in force than it is during subsequent years. The reverse is the case among men. Spinsters after the age of thirty are better risks than men. Married women, especially when the husbands are the beneficiaries, have a high mortality. Widows and divorced women have a high mortality before the age of thirty, but after that age the mortality seems to be but little increased above that of men.

The plan of insurance applied for seems to have considerable influence on the mortality. Those taking endowment insurance have a favorable mortality; those taking limited pay life have about 15 per cent greater; and those taking the whole life plan are very unfavorable risks.

If the husband is uninsurable the fact should be clearly stated, and the reason for his disability given. When a woman has children old enough to support her, a sufficient reason should be given for her desiring insurance.

Some companies do not issue insurance to women. Others do not restrict them except as to the amount. Some companies limit married women to endowment plans. Women, as a rule, are more easily disturbed about being declined than are men, and great care is exercised in the selection of women applicants for insurance.

The Ideal Work Curve in Industry

Studies directed toward the investigation of fatigue during the past few years have resulted in the construction of several typical work curves in industry. Curves have been evolved which make possible a comparison in the output in eight-hour plants as compared with plants requiring a ten-hour work day. Always a diminution in output indicates the onset of fatigue, the efficient worker in all cases being characterized by steadiness in contrast with the fluctuations, weekly and daily, of the inexperienced or inefficient worker. The quickest worker in all the studies was generally the steadiest. A variety of work on an operation rhythmic in nature produced a work curve which tended to rise throughout the day. When the hours of work were shorter and work throughout the week. It is through the precise observation of factors like these that normal curves are constructed as a basis for standards of performance.

A study of these work curves is made by Thomas Bedford in the *Journal of Industrial Hygiene* in favor of the proposition that there is probably an ideal work curve wherein under properly regulated conditions the worker concerned would start in the day at very nearly his maximum rate, and that, as time progressed, practice gradually increased his working capacity. The rise of the work curve would indicate the existence of a fine adjustment of the operative's working powers to his task, with a consequent elimination of undue fatigue. Bedford says: If human effort in industry is to be used to the best advantage, steadiness at work must be encouraged and useless spurring at the beginning of the day must cease.

Recent Compensation Decisions

BY DOROTHY KETCHAM, DIRECTOR, SOCIAL SERVICE, UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

A RELIGIOUS corporation selling burial privileges in its cemetery and devoting its net proceeds to religious or charitable purposes, according to the New York Court of Appeals, November 21, 1922 was not conducting a business for "pecuniary gains." Hence it follows that in an action against it by an injured employee it would not be deprived of these defenses because it had not come under the compensation law.

The respondent in the case was employed as a laborer in the Cathedral's cemetery. While he was excavating the foundation for a monument he was injured by negligence of the appellant. The employment was admittedly a hazardous one, and yet the appellant had not protected its employee under the provisions of the workmen's compensation law. The respondent brought action to recover damages a verdict being found for the respondent after, in trial, the judge held as a matter of law that questions of assumed risk and contributory negligence were immaterial.

The question is raised as to the correctness of the ruling, the court basing its answer upon Section 3 and 5 defining the terms employment to include "employment only in a trade, business of occupation carried on by the employer for pecuniary gain, or in connection therewith." Only in case the workman is engaged in an employment so defined, does the Act apply as stated in Section 10. In the opinion of the court the appellant was not engaged in business for pecuniary gain. It owned a cemetery and sold burial privileges for which it received money. "But for the one fact that money is received by the employer for property sold or privileges granted is not sufficient to bring him within the definition of carrying on business for pecuniary gain. We may concede that the regular sale of burial rights in a large cemetery to an applicant who agrees to comply with conditions imposed is a business. That is not enough. The purpose of the business must be profit. 'Pecuniary gain' as used in the statute merely means that the employer must be carrying on a trade, business or occupation for gain."

In the situation at hand there were no salaries, no dividends, no division of profits directly or indirectly.

"Substantially all the sums received are used for the maintenance of the cemetery. If, inevitably there is any surplus, it is used for the charitable objects of the corporation. To say it is engaged in business for profit is an abuse of language We attempt to lay down no general principle that will serve the test under varying conditions. We hold that the statute applies to a corporation engaged in a trade, business, or occupation carried on for pecuniary gain, and that the appellant was not so engaged." The decision of the lower courts was reversed and a new trial granted.—*Dillon v. Trustees of St. Patrick's Cathedral in City of New York*, 237 N.E., 31.

UNDER the compensation act, the Supreme Judicial Court of Maine, December 22, 1922 decided the following situation. Orff and his employer agreed on compensation for a fracture of the rib of the right side. This agreement was approved and later the insurance company raised the question of ending the compensation since "the injury for which the employee was compensated had ended." The chairman of the industrial commission refused to terminate compensation.

The court points out that in such proceedings under the compensation law, when the commissioner finds the facts favorable to the petitioner, in the absence of fraud, the finding is final, however slender the evidence sustaining it is. This is not the rule where the finding is against the petitioner. "When the court holds that the findings of the commissioner must be set aside because unsupported by evidence, it is not deciding facts. It is asserting the fundamental legal proposition that a trier of facts, acting in a quasi judicial capacity must not render decisions without evidence. But it would be a usurpation for this court to say to the tribunal, having by statute the exclusive right to decide facts, that it must accept certain testimony as conclusive."

The situation was that Abel Orff was on May 8, 1921 afflicted with an internal cancerous growth which was at the time dormant, causing no pain. He was at the time working regularly and without trouble. Without the accident his disability might have been postponed for some time but following

the accident he suffered constant pain and was incapacitated for work. "It was in effect agreed that his incapacity was caused by the accident."

"True his injury was diagnosed as a broken rib. True the cancerous condition was discovered after the making of the agreement. This changed the supposed character, but did not negate the fact of causal connection." The court dismissed the appeal upholding the decision of the commissioner since "the accident aggravating a diseased condition caused a disability which is not shown to have terminated." The man was entitled to compensation of the disability due to the fact that the cancer was aggravated or accelerated by the accident.—*Orff's Case*, 119 Atl. 67.

THE claimant, Andy Wilson, while in the employ of the Sun Coal Company, received an injury which produced hernia. The company proposed necessary expenses of care and operation which claimant refused to do, and his failure to submit to the operation was set up as a defense to his right to recover.

"The evidence shows that a party so injured can never do efficient work, and that the injury will likely become greater as time passes; that as a result of the injury the earning capacity has been reduced one-third; that the only cure for hernia is a surgical operation—that the claimant is physically able to undergo the operation, and an operation was recommended by the several physicians who examined him."

"Under these facts, we are of the opinion that the employer was within its right in demanding that claimant submit to the operation. Under the disputed evidence, we are impressed with the idea that any reasonable man, under such circumstances, would have submitted to an operation."

This does not mean that operation will be upheld in all cases but where the undisputed evidence and facts point to the advisability of an operation, as here, the court upheld the general opinion and "therefore, that petitioner is not entitled to recover compensation so long as he declines to submit to operation." Claimant is entitled to recover compensation from the date of injury until the time he refused to be operated on.—*Sun Coal Company v. Wilson*, 245 S.W., 547.

INSTITUTIONAL HEALTH

The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents

Feeble-Mindedness—State Policy of Control*

Connecticut Proposes Solution in Vocational and Supervisory Methods

BY ARNOLD GESELL, M.D., PROFESSOR OF CHILD HYGIENE AND DIRECTOR OF THE PSYCHO-CLINIC, YALE UNIVERSITY, NEW HAVEN, CONN.

FEEBLE-MINDEDNESS is an enduring problem. Its magnitude as a state problem has sometimes been exaggerated; more often it has been underestimated. Whether recognized or neglected, feeble-mindedness, in its own persistent manner, continues to exert a powerful effect upon the welfare of the community. The feeble-minded are with us and, like the poor, they will be with us for some time to come. They are a burden and, in a sense, a menace; but it is preferable to think of feeble-mindedness as a great human problem which, like tuberculosis, can be attacked and ultimately conquered by methods of science and ingenuity. The total weight of feeble-mindedness appears to be staggering; but attack the problem in its individual units, (as in the fable of the sticks) and it loses its hopelessness. Indeed, feeble-mindedness is one of the most concrete and manageable of our great social problems. The feeble-minded can never combine to defeat us; but we can adapt our family and community life in such a way that all concerned shall be mutually safe.

Who Are the Feeble-Minded?

A feeble-minded person may be defined as a person for whom the community must contrive special adaptations, to make up for individual constitutional deficiency of intelligence, intelligence being the measure of his capacity of mental adaptation. The feeble-minded by birth or misfortune,

The feeble-minded present a complex but practicable problem. The ground-work for control has been laid by pre-vocational training in the public schools. Auxiliary centers for specific training, followed by placement and supervision can gradually be developed as part of the state system.

Extra-institutional activities mean a simple extension of the functions of the public school, the juvenile court, and the state training school, vocational colonies having a distinct place in a balanced scheme.

Private agencies and welfare organizations contribute in the essential case work, in securing suitably adapted employment, and in safeguarding the conditions of employment. All social agencies must unite in the effort to solve the human problem of the feeble-minded.

possess this capacity in such an inferior degree that they can not maintain themselves successfully without external support, guidance, and supervision. They have mentality, they have personality, but inadequately for the ordinary demands of civic life. The idiot is all but helpless. The imbecile can guard himself against common physical dangers, but otherwise needs constant protection. Fortunately, idiots and imbeciles are defi-

nately in the minority. They are outnumbered perhaps three or four times by the moron or high grade defective who more closely approximates the normal yet always needs some protection and oversight.

How Numerous Are They?

For children, under eighteen years of age, in Connecticut, figures can be offered with some confidence, for they are based on first hand studies; they are round and they are most conservative: (1) Mansfield Training School and Hospital, 200; (2) homes for dependent and neglected children, 200; (3) institutions for delinquents, 200; and (4) elementary schools, 2,500; making a total of well over three thousand juvenile mental defectives for the state.

For adults it is much more difficult to supply statistics. The number of adults enrolled at the Mansfield Training School and Hospital would give us only a bare indication of the total number. To make a complete census we would have to go to the state hospital at Middletown and determine those of its inmates who are primarily feeble-minded, the insanity being in the nature of an associated or induced complication. The proportion is considerable. We should have to go to the prisons, jails, almshouses, where again the primary defect is often mental deficiency, crime and dependency being complications or mere symptoms; and highly preventable. We would have to go to the highways and byways of city streets and country roads, among vagrants, prostitutes, wastrels, and ne'er-do-wells:

*Presented at the annual meeting of the Connecticut Society for Mental Hygiene, Hartford, January 12, 1923.

failures in life because of inherent mental defect. Who will number them all? We would have to go into rural hovels, suburban shanties, and city tenements, miserable, shiftless homes, presided over by feeble-minded mothers who have been permitted to bear, and even to rear children. We should also have to go to everyday places, to factories, shops, farms, and domestic circles, where some sympathetic employer or understanding parents, or interested relatives or friends have made it possible for the feeble-minded person to maintain a simple, secure and even useful place in life.

The significance of these feeble-minded "successes" in life should be emphasized because they clearly demonstrate the manageability of the defective, and the possibility of bringing the whole problem under social control. We must be cautious about generalizations concerning the feeble-minded. The moron makes a failure of life only when he is not given a suitable opportunity, within his limitations, to make good.

Incurable, Not Irreducible

Feeble-mindedness is incurable; and in this sense irreducible, but only in this sense. One of the major causes of feeble-mindedness is feeble-mindedness. All eugenic measures which will insure soundness of stock, will in the next generation increase normality at the expense of subnormality. Sterilization has an extremely limited scope of application. The Connecticut law on the marriage of the feeble-minded unfortunately does not enforce itself. More efficacious is a social policy which, by means of segregation and supervision, will so safeguard the lives of the feeble-minded girls and boys, men and women, that they can not bear children either in or out of wedlock, and will prevent them from assuming the responsibilities of a family.

There are numerous cases of feeble-mindedness in which the causative factor is a disease or a damage which curtails the development of the brain. All medical and public health measures which promote maternal hygiene, which improves obstetric and midwife practice, and which control infectious diseases, will, in the aggregate, materially reduce the number of feeble-minded. But it will be a long time before we stop all feeble-mindedness at its source. While we strive for prevention, our immediate duty is to reckon with the feeble-minded who are actually with us or who are growing up before our eyes.

We can not at a stroke wipe out

feeble-mindedness, but we can cope with it, and defeat its most harmful manifestations. We can manage it. It does not represent such an overpowering act of God that we are helpless before it. Feeble-mindedness is a peculiarly human problem which needs for its solution the rare but attainable wisdom of common sense, and straightforward cooperative community action.

For the nearly helpless cases of idiocy and low grade and middle grade cases of imbecility our duty is only too obvious. They need hospital shelter with the same urgency that a foundling or an invalid needs asylum. From the most elementary standpoint of decency we should so increase our institutional provisions that every custodial case of mental defect will be properly cared for. Many of them are not only deficient mentally but blind and deaf, or crippled too. The long waiting list of custodial cases, on file in the Governor's office, ought at least to be stricken out by the General Assembly.

The vast majority of the feeble-minded are not custodial in the hospital or asylum sense of the term. This is fortunate, for society could scarcely bear the economic burden of placing them all in institutions. And even if we could build the institutions, we should have some difficulties with the running expenses, upkeep, attendants, and staff. Nor would it be a really humane or common sense solution of the problem.

The moron or high grade defective is a very human sort of person, who, though not entitled to all the rights and privileges of community life; is entitled to as many as we can with safety extend to him.

Governor Templeton struck the right note when, in his inaugural address, he called attention to the vocational aspects of feeble-mindedness. For the high grade, borderline defectives the key to control is vocational, vocational training, vocational placement, vocational supervision. Not by concentration of large numbers in institutions but by more flexible, individualized devices of local community control can we solve both the humane and economic elements of the problem.

If we deliberately supply secure and steady employment to the mental defective he can ordinarily remain in a local community, without inflicting those harmful social consequences which grow out of neglect. How can a program of vocational control be achieved?

First of all we must discover who the feeble-minded are, and a policy

that is truly constructive and preventive will begin with the children. Chapter 355 of the Public Acts of 1921 provides that the State Board of Education shall make regulations requiring the enumeration and reporting of all children over four and under sixteen years of age "who, because of mental or physical handicap, are incapable of receiving proper benefit from ordinary instruction and who, for their own or the social welfare, need special educational provisions." This includes not only the deaf, blind, and crippled, but the feeble-minded as well. The school census and the state control over the school registers of all elementary schools and the principle of compulsory education are of basic importance in this connection.

The division of special education which is now being organized should make an invaluable contribution to the control of the problem of feeble-mindedness in Connecticut. Our vast public school system is virtually a clearing house where many social problems can be recognized and coped with while they are still in a potential or premonitory stage. Surely it is so with the feeble-minded. To try to make them normal by persistent academic instruction is folly. To give them a practical, pre-vocational type of training designed to make them in the end useful and happy is at least the part of wisdom.

We ought not to exclude the ordinary defective from our schools; we should welcome the opportunity to train him. Special classes for groups of defectives in our cities and special programs for the individual defectives in county and village, constitute the first step in a system of vocational control. Even the child in a remote district school can be reached by special methods of educational inspection and state aid. It would be a good investment and a sound social practice for the state to give special educational grants to encourage and support the training of the public school feeble-minded while they are in the plastic stage of their development. We must continually remind ourselves that the overwhelming majority of our juvenile feeble-minded are now actually attending our elementary schools.

County Home Schools

In very disproportionate numbers they are attending the schools attached to our county temporary homes. The educational interests of these wards are definitely under the supervision of the state board of education.

This raises some vital questions and possibilities concerning the future functions of our larger county homes.

The law that established these homes clearly stated that no child should be detained there longer than absolute necessity should require. Under the administration of the new bureau of child welfare there has been a marked and most commendable reduction in the number of commitments to county homes. A progressive effort will be made to place neglected and uncared for children in family homes; and in a very few years this should result in a marked decline in the enrollment of our county homes. If in addition we should rigorously exclude all the mentally defective and mentally subnormal, the enrollment would become very small indeed.

For a time the New Haven County Home conducted a special room, under a special teacher, for the special training of the defective pupils. If we followed out the implications of this demonstration we should in time frankly consider the desirability of setting aside at least one county home as a residential, vocational training center for juvenile feeble-minded. The county homes do not commend themselves to citizens of Connecticut as residential schools for normal children deprived of parental care; but the problem of the defective dependent is clearly a different one. Inasmuch as dependency, neglect, and feeble-mindedness are so frequently associated, we can not leave the county homes out of any complete program of vocational control which may be evolved. With the cooperation of the state board of education and the bureau of child welfare, one of our county homes could, without violence, be converted into a center for occupational training, for special vocational placement and social supervision.

That the higher grade of the feeble-minded can be trained for productive labor in industrial, agricultural, and domestic fields has been demonstrated beyond all dispute. It has also been demonstrated that after preliminary training a small group of some forty mental defectives can be placed in a rented house, presided over by a matron and her husband; and that with this dormitory serving as a home and recreation center, these defectives can go out and do housework, farm work, and shop work. There are over thirty of these extra-institutional vocational colonies in New York and they are being operated at a tremendous economic saving to the state.

How this and similar kinds of vocational control can be developed in

Connecticut is a question of complex but practicable detail. The ground work for such a policy of vocational control has been laid. The public schools must furnish the basic pre-vocational training through special programs, special teachers and special classes. Auxiliary vocational centers for specific training, specific placement and supervision must gradually be developed as part of a state system and not altogether independently of the public school and of the juvenile court. In all this extra-institutional activity the Mansfield State Training School has a rôle to play; and particularly in connection with parole and with the establishment of vocational colonies.

There is also abundant room for effort on the part of private agencies and welfare organizations. Careful social case work pays even with the feeble-minded. The finding of proper employment, the safeguarding of the conditions of employment for a feeble minded youth is a constructive form of social work. Private individuals, professional social workers, local committees, "Big Brothers," "Big Sisters" and our state society for mental hygiene have here a concrete field for cooperation accomplishment and civic inventiveness. We have not yet unlocked the local community resources which will solve the human problem of the feeble-minded.

Urge Cut in Criminal Birth Rate

"Eugenical Sterilization in the United States" is the title of a book by Dr. Harry Hamilton Laughlin, D.Sc., assistant director of the eugenics record office of Cold Spring Harbor, Long Island. The immediate stimulus to the preparation of this book has been the service of the author as eugenics associate of the psychopathic laboratory of the Chicago Municipal Court.

An introduction by Chief Justice Harry Olsen states that:

Sterilization, as a supplement to the eugenics marriage laws and to the segregation of criminals has already been in force for a number of years in fifteen states. Individuals unfit to have offspring often volunteer to be deprived of their reproductive powers, and in other cases are sterilized, by a simple and harmless operation by a judgment of court.

The subject of sterilization comes to the front with special force now in view of a model sterilization law which has been drafted and will be offered generally to the legislatures of the forty-eight states. The new law is a vast improvement upon the hasty

and experimental legislation which has preceded it.

The psychopathic laboratory of our court has had unequalled opportunity for studying criminals individually and collectively, for in the past eight years many thousands have been examined psychologically, physiologically and anthropologically. When the laboratory was opened the most advanced thought in respect to criminality was that low intelligence was a chief factor.

It has been proved by thousands of cases that the dangerous criminal is dangerous, not so much because of low-grade intelligence, as because of low-grade emotions and low-grade morals. There is nothing in him to tell him that he will suffer if he makes others suffer. He is potentially dangerous under all circumstances and if his intelligence is too low to permit him to make a living in the ordinary ways he naturally resorts to crime. Such individuals must be segregated, not merely interned for a short term in prison, and some of them may have to be sterilized in order to make sure that their numbers are not increasing from generation to generation.

Scoring the House and the Community

The score card principle, now used for many purposes in health work, is applicable to comparisons of many kinds. The Morgantown, W. Va., Chamber of Commerce has issued a Community Score Card which in a slightly different form has been used in about one hundred and twenty communities of the state.

The card provides for a possible one hundred points on each of the following: the municipality; trade center; prosperity; social; health; education; recreation; fine arts; religion; and community spirit. The sub-divisions together with the possible number of points allowed in scoring the health of the community are: physicians and dentists —15; hospitals and trained nurses —15; public health service —30; sanitation —30; and public interest —40.

In a "Questionnaire and Score Card Applicable in Choosing a Country Property," by William Paul Gerhard, fifteen factors having a total possible score of one hundred points are listed as those demanding careful attention before the purchase of such property.

Some of the factors having a more or less direct relation to health are given the following possible scores: physical conditions and climate —5; water supply —10; sewerage, sewage disposal, and removal of refuse —10; milk supply —5; medical and nursing service —5; and outdoor and indoor recreations —5; making a total of forty points out of the hundred that would be scored by a perfect property.

Deafness in School-Children

The subject of deafness in school children is usually accorded less attention than it deserves, particularly in view of the fact that formal education to be effective must begin much earlier with deaf children than with the normal child. Some interesting observations on the subject have been recently recorded by the *Lancet*.

It may not be wise to leave the detection of deafness in school children to their teachers, however conscientious. This is the lesson taught by Dr. F. Leegaard, who was appointed in 1919 by the school authorities in Christiania to examine the ears of children attending the public elementary schools. Among 4,721 children in third school year he found 459, or 9.7 per cent suffering from some degree of deafness, which in 119 cases was bilateral. In more than half the number of unilateral and bilateral cases the teachers proved to have been unaware of this disability, and the children therefore ran the grave risk of being transferred to special institutions for the mentally deficient, whereas their imperfect hearing qualified them for the special educational facilities provided for the deaf.

It was found that chronic suppurative otitis was present in 1.4 per cent of the 9,442 ears examined, and in 2.5 per cent of the 4,721 children. Chronic otitis was found in 22.1 per cent of the 578 deaf ears and in 25.3 per cent of the 459 deaf children, and in most of these cases of chronic otitis hearing was more than a little reduced. In 1.7 per cent of the 9,442 ears dry perforation of the tympanum was found, and was associated with some degree of deafness in 1 per cent. Among the 578 deaf ears the incidence of defects of the tympanum was as high as 17 per cent. In most of these cases, however, the deafness was only slight or moderate. Scars of the tympanum were found in 1.7 per cent of the 9,442 ears, and in 0.31 per cent they were associated with some degree of deafness. These defects were found in 5 per cent of the 578 more or less deaf ears. Tubal catarrh was demonstrable in 24.7 per cent of the 578 deaf ears, and the cause of the deafness was traced to acute otitis in 2.4 per cent and to cerumen in 7.9 per cent. In as great a proportion as 2.8 per cent of all the deaf ears no disease of the tympanum could be found, and no definite diagnosis could be made. One of the by-products of Dr. Leegaard's systematic examinations was the discovery that, between

the ages 9 and 10, the incidence of adenoids and enlarged tonsils was remarkably high and was often unassociated with deafness or any other departure from ordinary health. It is evident that Dr. Leegaard's work has fully justified the course taken by the Christiania school authorities in appointing a specialist in disease of the ears to the school medical service.

Dietetic Courses for Pupil Nurses

Standards of dietetic instruction for pupil nurses in Class "A" hospitals have been ascertained by a questionnaire sent to 422 hospitals in the United States and Canada, 48 per cent of which replied. The study was undertaken by Miss Helen Clark for her thesis for the degree of Master of Science, Ohio State University.

Inductions which may be made from Miss Clark's study include the following: (1) hospitals do not have a minimum standard of educational requirements for dietitians; comparatively few instructors have had courses as student dietitians; (2) so far as the answers to the questions indicate the duties of the instructors are nearly uniform in each hospital; (3) methods of instruction are very similar in all hospitals; (4) there are no definite years when classroom or lab-

oratory work are given and these classes are often not concurrent; classroom work usually precedes that given in the diet kitchen; (5) most of the schools use a textbook for class instruction in dietetics; fewer use a laboratory manual; an outline for the diet kitchen work is generally used; (6) opportunity for giving work in the laboratory in preparing special diets, infant formulas, preparing diet lists, making menus and purchasing food supplies is not used to the extent which is easily possible by the laboratory classes; (7) practically one-third of the instructors feel that the average nurse dislikes dietetics.

Wichita, Kas., has 47 basketball teams, 6 bowling teams, 31 men and 15 women baseball teams, 7 tennis teams and 6 track teams, reports *Physical Training*. Twenty-four churches were represented in from one to 10 different sports. A total of 3,514 men and women participants and 9,700 spectators at contests is recorded. Volunteer workers numbered 287 and 30 gymnasiums and play fields were available for the contests. This widespread physical education program in a city of 75,000 was started five years ago when Mr. Ireland, physical director, Y. M. C. A., organized an 8-team Sunday school basketball league.

A Three Weeks Health Demonstration

Interest attaches to the New York City experiment in a scientific feeding régime of thirty-six children undertaken as an object lesson to the parents of the two hundred thousand children whose state of malnutrition constitutes a health menace, present and potential. Food a plenty of the right kind is combined with suitable activities and open air conditions to give these handicapped children a new start in life.

Standardization of Student Health Service

Physical Director, Hygiene Teacher,
Sanitarian and Doctor Must Cooperate

By J. E. RAYCROFT, M.D., CHAIRMAN COMMITTEE ON STANDARDIZATION AND EVALUATION OF STUDENT HEALTH SERVICE ACTIVITY, AMERICAN STUDENT HEALTH ASSOCIATION, PRINCETON, N. J.

STANDARDIZATION and evaluation of student health service activities may be profitably discussed for three principal reasons: First, to assist college authorities to visualize the many factors that affect student health and to bring to their attention their responsibility to make adequate provisions for keeping students in good, permanent, healthy condition.

It also devolves on the college authorities to administer their affairs as regards their students in such a way that wastage of endowment funds will be as little as possible, the wastage due to the inefficiency of the students who are under their charge.

The second point is to outline the general principles that must be observed in any attempt to set up an efficient organization to deal with this important phase of the college responsibility; and third, to define in general terms, the relationship between the physician who is in charge of the health service and the physical director.

An analysis of the typical student community will show that there are, generally speaking, two sets of factors affecting student health, environmental and personal. The first includes (1) General sanitation of buildings and surroundings as regards sewage disposal, mosquito breeding, noxious gases, inefficient janitor service, etc. (2) Conditions in dormitories, class rooms, and laboratories as regards light, both natural and artificial, heat, ventilation, bathing, lavatory and toilet facilities. (3) Food and water supply in Commons and boarding houses; protection against infected milk and disease carriers. (4) Provision for treatment in dispensary and infirmary. (5) Provision for healthful exercise and recreation.

In the second group will appear (1) the student's physical status; his present condition and tendencies in the light of his past experience as shown by physical and medical examinations. (2) his knowledge of the principles of personal hygiene and his practice of health habits; (3) his habits of exercise and recreation. (4) supervision of his participation in

competitive games and other extracurricular activities; (5) requirement of protective vaccinations, inoculations, etc.

These factors are susceptible of rearrangement in various groups such as educational, sanitary, medical or physical training, but, inasmuch as the fundamental problem is promotion of student health and efficiency, and the basic factors are much the same in all places, the essential point is to suggest an effective plan of organization and administration. Most of the institutions throughout the country have some or all of the necessary individuals or facilities, so that a decision to establish a "student health service" might be put into effect in three steps: by organizing a student health board, on which hygiene, sanitation, medicine, and physical training shall be represented; by analyzing the contribution which each of these individuals or groups can make to establish and carry on the service; and by organizing a cooperative working plan among these different groups and individuals.

The decisions made as a basis for these various steps must be divorced as completely as possible from departmental organization, as such. In other words, effort must be made to find the individual or department best qualified to perform a given function.

It will be necessary and helpful to formulate in clear terms the particular objective of each phase of the work. For example: (1) What grounds should be covered in a course in personal hygiene and where should emphasis be laid? (2) What list of observations in a physical examination is capable of supplying information most useful both to physical director and doctor in charge of the hospital.

If these and other objectives are clearly formulated and there exists an appreciation of the need and importance of a well organized student health service to which physical director, doctor, laboratory man, teacher of hygiene, and sanitary inspector all contribute, I believe that there will be a minimum of friction and misunderstanding.

Another point to be noted is that

physical education is a constructive set of activities for the normal individual while the health service primarily has a curative and medical purpose.

FORM OF HOSPITAL REPORT PRINCETON UNIVERSITY

	1914-15	1920-21
Total number undergraduates.....	1,643	1,967
Infirmary open, days.....	267	264
A. Dispensary:—		
1. Patients treated:		
a. Seniors	259	277
b. Juniors	232	374
c. Sophomores	293	376
d. Freshmen	301	378
e. Post Graduates and Faculty	108	63
f. Seminary	69	48
g. Employees	17
h. Outsiders	13	61
Totals	1,275	1,594
2. Number of treatments.....	6,895	11,994
3. Average number treated daily in Dispensary.....	25.8	45.09
4. Average number of treatments per patient.....	5.4	7.3
5. Largest number treated in one day	68	94
6. Percentage of undergraduates treated	75.9	77.4
7. List and number of diseases treated (To be reported later)		
B. House Patients:—		
1. Number of patients.....	552	570
2. Number of students sick in bed more than once during year:		
2 times	64	67
3 times	14	16
4 times	4	2
5 times	1	0
Totals	83	85
3. Number of contagious cases isolated (included above)		
a. List and number of infections:		
Mumps	33	23
Diphtheria	1	0
Scarlet fever	4	2
Measles	1	4
German measles	1	0
Chicken pox	3	4
Typhoid	4	0
"Pink eye"	0	77
Totals	47	110
b. Largest number of students isolated at one time	14	11
c. Largest number of different infections isolated at one time	3	8
d. Number of cross infections	1	0
4. Number of operations and general anesthesia:		
Major	7	3
Minor	0	14
5. Special Nursing:		
(1) Number of Days:		
(a) Staff nurses	615	293
(b) Outside nurses	172	369
Totals	787	662
6. Results of treatment:		
a. Patients recovered	534	531
b. Patients transferred to home or another hospital	17	18
c. Patients died	1	1
7. Total number of patient days	2,922	2,934
8. Average number of students per day sick in house	10.9	11.1
9. Average number of days each patient sick in house	5.3	5.14
10. Largest number of patients in house in one day.....	26	29

11. Percentage of students sick in hospital each day, of 16	66%	56%
12. Total loss in time from sickness in bed, in terms of college years of 240 days each	12.2	12.2

It is to be noted that number of students sick in bed throughout the year was only slightly larger last year than in 1914-15, in spite of the fact that there was a 20 per cent increase in the number of students attending college, and the further fact that we have followed the plan of putting students to bed for twenty-four or forty-eight hours as a preventive measure in certain cases.

We think that the increased use of the dispensary is in large measure responsible for this reduction in the amount of sickness in bed, because it affords an opportunity to abort many simple infections and to make an early diagnosis of more serious cases.

Drastic Rules for the Control of Venereal Diseases

Members of the state health advisory commission of Illinois declare that the new set of rules for the control and suppression of venereal diseases, promulgated by Dr. Isaac D. Rawlings, state director of public health, are more drastic and advanced than similar regulation in any other state in the union. The commission has approved the rules which, under the authority granted the state director of health by the legislature, have the force of law and are backed up by a penalty clause which subjects violators to a fine of two hundred dollars, a jail sentence of six months or both.

The *Chicago Tribune* summarizes the three regulations which make the most drastic changes in the old venereal disease rules as follows:

All persons who have exposed themselves to venereal disease but who are not found to be infected, may be held by local health authorities as "suspected contacts" for the period of incubation of the suspected disease—ten days in the case of gonorrhea and thirty days when syphilis is suspected.

Refusal of a suspected person to submit to examination by health authorities "shall be *prima facie* proof that such person is infected and shall authorize and justify quarantine and isolation of any such person and the placarding of the premises," another rule states.

No physician or other person shall issue certificates of freedom from venereal disease to any person known to be or suspected of practicing prostitution, under another rule.

Under pain of revocation of their licenses to practice medicine, this third rule will put an end to the lucrative practice of some physicians of examining inmates of disorderly

houses "at so much a head" and issuing health certificates to them.

Rule 7, which gives authority to health officers to deal with "suspected contacts" is as follows:

"Any person known to be a common prostitute . . . or any man consorting with a common prostitute or inmate of a house of ill fame caught in association with a common prostitute or inmate of a house of ill fame shall be deemed to be a suspected case of venereal disease or an infective carrier."

Names, addresses, sex, age, color, marital condition, occupation, and the name and address of the infected person's employer, must be given under the new rules.

Druggists who sell preparations for the cure of venereal diseases are required, under Rule 8, to report by name and address purchasers of such preparations unless the purchase is accompanied by a physician's prescription.

Under Rule 17 local health authorities may define the limits of the area in which diseased persons are to be isolated. This rule also specifies that such persons may not handle food-stuffs, work in a barber shop, or practice medicine, dentistry or nursing.

Full authority is given for the placarding of both suspected and known cases of venereal disease and blanket power to placard "premises used for

immoral purposes when such premises are known to harbor or are suspected of harboring a person afflicted with venereal disease" is also given health officials.

Gymnastics for Infants

Gymnastic exercises for infants have been worked out and found to be beneficial by Detlav Neumann, former army officer and athletic director in Berlin, reports the *Journal* of the American Medical Association.

A well padded table large enough to allow the child to tumble about on but small enough so that the assistant can control the child's movements with his hands is used. The system has been tried on both healthy and sick infants with the aid of Professors Bier and Langstein. Incipient cases of rickets have been benefited and weak musculature of children who have learned to walk late has been strengthened. The benefits of gymnastic work for infants are not confined to corrective measures, but are most pronounced in the balanced development that ensues from consistent training in efforts toward muscular coordination.

Woodmen Memorial Sanatorium

WOODMEN of the World is building a sanatorium for tuberculous members of its order in San Antonio, Texas, announces W. A. Fraser, Omaha, Neb., sovereign commander. One hundred thousand dollars was appropriated by the national organization and Texas members donated a similar amount.

The Bexar county farm, bought by the organization as the prospective site, is located on a high hill overlooking San Antonio. The first unit of the sanatorium will be a building 300 feet long and three stories high with an elevator going up through the center of the building sufficiently large to accommodate wheel chairs, wheel cots, and stretchers.

The building will be of concrete and brick with 300 feet of reinforced concrete porches on each floor making a total of 900 feet of porch room which will accommodate 125 patients. An administration building will be erected at a later date together with a residence for the chief medical director and sleeping quarters for help.

Water supply will be from deep wells. Two dairy barns are already on the property; chickens will be raised in large numbers; and fresh meats secured from the city daily. The ground is well adapted to farming and

truck gardening; the fresh vegetables necessary can be raised throughout the entire year.

The hospital is being built as a war memorial to members. On a monument to be erected in front of the main building will be engraved or cast on bronze plates names of all those in the order who lost their lives in war.

Mr. Fraser, then sovereign adviser, began the movement in 1907 for a tuberculosis sanatorium for members when \$8,000 was subscribed for relief purposes. In 1909 the order made arrangements whereby members could secure treatment from the Texas Sanatorium, Carlsbad, Tex. The campaign for the national sanatorium began in 1919 when the convention appropriated \$100,000 to be used whenever the first state whose climatic conditions were favorable for treatment of the tuberculous contributed a like amount.

As soon as the sanatorium is established, Woodmen of the World will begin a campaign for a sanatorium in the east for aged members. Proposal is that each state in the union furnish certain rooms to be named for the state and set aside for members from that state. Erection of an orphan's home is also being contemplated.

Diphtheria Control in Custodial Institutions

Disease Controlled by Toxin-Antitoxin Treatment Given to 5,000 State Wards

By DON M. GRISWOLD, M.D., M.P.H., STATE EPIDEMIOLOGIST, DEPARTMENT OF HYGIENE, UNIVERSITY OF IOWA, IOWA CITY, IOWA.

THE Board of Control of State Institutions in Iowa has supervision of all institutions of the state except those used for educational purposes. The institutions under the supervision of this Board are hospitals for mental disease, reformatories, industrial schools, institutions for feeble minded, orphans' home, soldiers' home, colony for epileptics and penitentiaries. The nature of some of these institutions requires the housing of large numbers of individuals under close supervision. Because of the differences in age and other factors, the incidence of the contagious diseases varies greatly.

With regard to diphtheria, one institution reports that they "have had no diphtheria for twenty years." From another institution the superintendent reports that "diphtheria quarantines have existed almost the year round." Because many of these institutions are not hospitals but institutions built and organized for the custodial care of infants and adults, the establishment of quarantines causes considerable additional expense and disruption of institutional routine.

More Modern Methods

It was with some of these things in mind that the State Board of Control of State Institutions inquired of the state epidemiologist if the application of the principles of modern preventive medicine would help to reduce this preventable illness and expense.

In the autumn of 1921 a visit was made to two institutions where diphtheria was prevalent. At this time the usual measures were instituted to prevent the spread of the disease to those not already attacked. These methods included the culturing of the throats of all the children in the institution, the segregation of carriers, quarantine of cases and possible cases, and in general the breaking of contact between the sick and the well.

At the same time all the children except those who had recently received antitoxin were given the Schick test. It was felt that this was an important step because as soon as the test was completed the children could be definitely grouped, as susceptible

or immune to diphtheria. This information made it possible to concentrate attention upon the susceptibles.

The fact that a child who is immune to diphtheria may be a carrier of the diphtheria bacillus was brought very forcefully to our attention in this outbreak. Children whom we knew to be carriers for a longer period than the incubation period of diphtheria were in every instance found to be immune. This finding is in accord with our previous observation on this matter.

The Schick test was not given to any child who had received diphtheria antitoxin in the three months previous to the work. The passive immunity granted by such administration would interfere with the accuracy of the test for at least that long. By the time the Schick tests had been given and satisfactorily read and recorded, a week had elapsed. During this week the measures toward preventing the further spread of the epidemic had proved effective and there were few new cases occurring.

The desirability of giving each susceptible child the advantage of toxin-antitoxin immunization was laid before the superintendent. Care was used not to hold out hope of any immunity from this procedure for at least three months. By carrying out vigorously the well established principles and procedures of epidemiology, the acute outbreak of diphtheria was stopped.

The interest of the permanent staff of the institution in diphtheria prevention work that was stimulated at this time continued to be operative for a sufficient time to permit the toxin-antitoxin administration to have successfully protected those found susceptible.

During the twelve months following this work there were no cases of diphtheria at these institutions except among those who had not received attention with the Schick test and toxin-antitoxin and among the new arrivals.

The Board in Control of State Institutions of Iowa was sufficiently impressed with the work in the two institutions in the fall of 1921 that an invitation was extended to apply the

same principles to eight other institutions under its jurisdiction during the summer of 1922. At that time we examined, as described, over 5,000 persons in the various state institutions, ages ranging from one month to 93 years. The age distribution was not that found in a general population.

The recommendations which were left with the superintendents at the close of this study contained among other things the following:

On admission, every child should be quartered in an observation ward for two weeks. Besides giving opportunity to study the child's mental and moral equipment, it gives sufficient time for making a complete physical examination and the incubation of any communicable disease the child may be bringing. Physical examination should include a culture of the nose and throat and all abnormal discharges. It should include vaginal smears of all girls under twelve years of age. During this two-week period the child should be immunized against smallpox and typhoid fever. The child should be given a Schick test and if found susceptible to diphtheria, should be given toxin-antitoxin.

Observation Periods

By admitting children into the institution only after a two weeks study similar to the one outlined, contagious disease can and should be kept at a minimum. Chickenpox, measles, and mumps are the only common diseases of childhood whose incubation period exceeds two weeks. It is only the occasional case of these diseases that has an incubation period longer than two weeks. Where experience showed it advisable, a three week period might be used. After such examination and care the population of the institution would be made up of persons naturally immune to diphtheria and those who had been made immune by toxin-antitoxin administration.

The study showed that the percentage of positive Schick tests ranged from 23 per cent to 54 per cent in the various institutions. The significance of this, is, of course, that regardless of age and other factors one-fourth to one-half of these wards of the state are susceptible to diphtheria.

Nearly one thousand complete treat-

RESULT OF SCHICK TEST AND TOXIN-ANTITOXIN WORK IN IOWA STATE INSTITUTIONS DURING THE SUMMER 1922.

Name of Institution	Type of Patient	Range in age	Number receiving Schick	Number Positive	Per cent Positive	Number given toxin-ant.	Reaction
Soldiers' Orphans' Home, Davenport, Ia.	Normal	9 mos. to 16 yrs.	360	90	24%	90	Severe, 15 local and constitutional.
Juvenile Home, Toledo, Ia.	Normal	1 yr. to 12 yrs.	129	27	24%		
Independence State Hospital, Independence, Ia.	Insane	years 14-93	1197	341	30%	341	Few mild local and constitutional.
Mt. Pleasant Insane State Hospital, Mt. Pleasant, Iowa.	Insane	14-93 years	1000	231	23%	231	7 severe and constitutional, 5 moderate local and constitutional, 14 severe local.
Training School for Girls, Mitchellville, Iowa.	Unstable	12-18 yrs.	204	110	55%		
State Hospital and Colony for Epileptics, Woodward, Iowa.	Epileptic	4-50 yrs.	429	244	54%	244	8 severe and local constitutional.
Institution for Feeble-Minded, Glenwood, Iowa.	Feeble-minded	1 mo.-65 yrs.	1523	454	32%		
Training School for Boys, Eldora, Ia.	Unstable	12-18 yrs.	331	90	27%	90	45 very mild constitutional.

ments of toxin-antitoxin were given. Only 30 individuals in this number reported "severe local and general reaction." This usually constituted symptoms sufficient to warrant the patient staying in bed the day following any one of the three injections of toxin-antitoxin; 5 reported "moderately severe local and constitutional reac-

tions"; 14 reported "severe local reaction," and a few more than 45 reported "very mild local and constitutional reactions."

The expense of the work and the suffering of the patients was infinitesimal compared with the expense and suffering involved in a few cases of diphtheria.

Institutional Problems of Building and Equipment

A series of articles appearing in the March issue of *THE MODERN HOSPITAL* constitutes a symposium on the subject of the physical plant of the hospital. Whatever the conception of the work by the personnel of an institution, however emergent the need, the delivery of medical service hinges largely upon the machinery through which it can operate. For this reason a comprehensive treatment of the subject is opportune and the solutions suggested by experts in their several fields will find an even broader field of usefulness in related institutions than in the hospital proper.

Titles are as follows:

The Building Outlook in 1923, by

Edwin J. Brunner, editor, *The American Contractor*, Chicago.

The Modern Hospital in the City Plan by Philip W. Foster, associate of John Nolen, one of America's outstanding city planners.

Relative Cost of Hospital Construction and Equipment by Dr. S. S. Goldwater, hospital consultant and director of Mount Sinai Hospital, New York.

Converting an Old House into a Hospital by Carl A. Erikson, of the well-known hospital architectural firm of Schmidt, Garden & Martin, Chicago.

The Interior Decoration of the Hospital by G. B. Heckel, editor and publisher, *Drugs, Oils and Paints*, Philadelphia.

General Principles of Planning Dis-

pensaries by Michael M. Davis, Jr., Ph.D., executive secretary, Committee on Dispensary Development, New York.

The Hospital Morgue and Autopsy Room by Richard Resler, of the firm of Resler & Hesselbach, architectural and consulting engineers, New York.

The Planning of Nurses' Homes for Small Tuberculosis Sanatoriums by Sund and Dunham, architects, Minneapolis, Minn., specialists in the planning of tuberculosis sanatoriums.

The Laboratory Quarters and Equipment of The Modern Hospital by Max Kahn, M.D., Ph.D., director Department of Laboratories, Beth Israel Hospital, New York.

Heating and Ventilating Considered in Connection with Hospital by Helen R. Innis, of the Donnelly System Company, New York, N. Y.

Do You Know These Facts?

The following queries from the *Mental Hygiene Bulletin*, January, 1923, give food for thought.

DO YOU KNOW THAT

There are 250,000 patients in hospitals for mental diseases in this country.

Each year 50,000 persons are admitted to these hospitals for the first time.

There are many cases of serious mental maladjustment that never reach these hospitals.

Patients with one type of mental disease alone (dementia praecox) are twice as numerous as persons in all hospitals for tuberculosis.

One man out of every six received into a state hospital for mental diseases for the first time is admitted on account of syphilis.

Over one-eighth of the total expenditure of some states is for the insane.

The expenditures for the insane in some states exceed the amount for any other purpose except education.

The cost of maintenance of persons in hospitals for mental diseases throughout this country is about \$75,000,000 annually.

The economic loss to the United States each year on account of mental diseases is over \$200,000,000.

The number of hospital beds occupied by patients with mental diseases exceeds the number in use in all general hospitals in this country.

Whereas most hospitals for mental diseases are overcrowded, the average daily number of patients in general hospitals is about one-half of the number of available beds.

From August, 1914 to June, 1919 there were 40,000 deaths from pulmonary tuberculosis (30,000 deaths throughout the Provinces of France and 10,000 in the army). In addition, 110,000 men were discharged from service for the same cause.

Clinic Maintains Child Health Theater

University of California Playroom Teaches Health to Waiting Children

BY MRS. JOHN COLLIER, ASSISTANT DIRECTOR, CHILD HEALTH ORGANIZATION OF AMERICA, MILL VALLEY, CALIF.

A DELIGHTFUL surprise awaits the children paying their first visit to the clinics of the University of California in San Francisco. As they step into the entrance hall of the big clinic building a gay poster of the clown Cho-Cho directs them to the Children's Health theatre.

Shedding self-consciousness, or fear of the doctor, they mount the stairs only to be greeted by a jolly younger brother of the knowing clown on the lower floor who bids them "Stop," with the proud gesture of the traffic cop, then commands, "Learn My Health Rules." Beyond Cho-Cho Junior, on either side of a broad hallway they see an array of small heads, black, brown, red and golden, all bent over low tables. On a busy clinic morning thirty or more youngsters will be seated at the long tables at work with crayons, pencils, plaster-sene, jigsaws, scissors, and paste-board.

As the new-comers stand fascinated a pleasant faced young woman in a blue smock explains that while they wait their turn to meet the doctor, they may play in the "health room."

Mother is asked to be seated in the "theatre" where she may save a seat for her children for the marionette show that will begin at 11:00. The mother presents her clinic card at the window of a real truly "theater en-

trance," inscribed in bright colors with the legend "Children's Health Theater," only the ticket man in this instance is a white capped nurse who assigns her patrons to the care of the proper doctor, and notifies parents and children when it is their turn.

Mother looks back doubtfully at her off-spring. Hand in hand with the blue smocked lady they are making a solemn tour of inspection, choosing what they will do. She sees her nine year old girl take her place in a group of girls who are furnishing a doll house. But what will her irrepressible seven year old boy choose? He finds a train of cars and some tracks set up in a sand box. With a sigh of relief she seats herself in the theatre, takes out her tatting, and settles down for the first bit of comfort she had ever hoped for—in a clinic.

Clocks Tell Health Schedule

Mother works undisturbed until her two come running with the plea, "Give us ten cents. All the kids out there are getting milk, just like soda water, with a straw. We want some too." The amazed mother argues that they never drink milk, that it does not agree with them, that on the way home they will stop at the "5 and 10" and get two big bags of candy with that ten cents. But the children insist that all the others are drinking milk and they want to too. Incredulous, she follows to watch the children sipping milk through straws from miniature milk bottles and munching graham crackers. "They'll be sick tonight, sure," she mumbles disapprovingly. "I never give them milk."

Before the marionette show begins the children return again, and cuddling, one on either side of her, both talk at once. "This is a picture of Cho-Cho. He's running a race with this boy and girl to see who can weigh the most each month. The teacher out there says that we can race too if we follow these rules. They're all about going to bed early, and drinking milk, and eating lots of vegetables. The teacher says we can come back here once a month and play some more health games, and be weighed. Why don't we have green

vegetables? You never give us anything but potatoes."

Before the amazed mother had time to respond, another blue smocked lady is announcing the beginning of "Mary Gay's Bed Time Adventure," and the marionette play is on. Fascinated, mother and children watch the amusing antics of the dragon, and of "Late Hours," the jewel thief, and deeply sympathize with Mary Gay, and the Fresh Air Sprite, and charming little "Early to Bed."

When the show is over, and the nurse directs mother and children to the examining room of the doctor to whom they have been assigned, both boy and girl forget to be afraid of this big white-aproned stranger. Instead they want to tell him all about Mary Gay and the dragon. After he has given the examination, and directions for treatment, the mother and children are not at all surprised when he presents each child with a long white card decorated with tiny clock faces, entitled, "Boys! and Girls! Play the New Health Game Every Hour of the Twenty-Four." With his fountain pen he fills in the hands of the two empty faced clocks, giving the time for each child to start to bed and the time to be in bed. He then explains directions printed under the other clock faces—what to do at 7:00 in the morning; what to eat for breakfast; what

Cho Cho directs children to the health theatre where marionettes perform daily.

The House that Health built constructed by children waiting their turn in the clinic.

By colored crayons, jig saws and plastersene the lesson of health is taught entertainingly. The interested children at once translate maxim into practice.

The marionette play "Mary Gay's Bedtime Adventure" in which are cast Late Hours, the jewel thief, Mary Gay, the fresh air sprite, and little Early to Bed.

to eat for dinner; and so on through the simple list of health habits.

When he speaks of the need of one quart of milk a day for every growing child, and of the delicious ways spinach, cabbage, and other leafy vegetables can be cooked, the children nod their heads wisely. The teacher outside had told them of that. When he finally says they can come back to see him the following Saturday, the boy exclaims, "Gee, we can beat those other kids out there. We will get weighed next week, and learn a whole lot more about health."

What has been happening in that "Health Play Room" to have so aroused the enthusiasm of these young patients? Doll houses, trains, jig-saws, scissors, and plastersene—how do these rainy day "life savers" connect up with the monthly gain in weight? These devices are of the child's world. Speaking in terms of them is speaking the child's language. They can be so used as to interest children in the practice of health habits, whose goal is not a lonely throne in a far-away heaven, but an immediate reward in ounces and pounds.

Ingenuous methods for indirect health teaching are employed at the Children's Health theatre. As the girls set to work to build their doll house out of four shoe boxes, the director of the play room helps them decide that the four most important rooms are bedrooms, bathrooms, kitchen, and dining room. As the little girls fashioned their furnishings, the director drew from the group facts about their own home use of these rooms, until together they had worked out the health habits that should be practiced in each room.

But far more important than the

discussion of health habits, that the director had called forth is the appealing picture of the rewards of health she has helped them build in their own minds as their busy fingers worked with card-board and scissors. The enjoyment of health is pictured in terms of rosy cheeks, glossy hair, and graceful carriage of body; in terms of "bubbling over," good spirits, and the vigor of mind and body that gets the most out of work and play. Health, Strength, Joy—skillfully the director makes these abstractions real for the children.

When children in a group are offered the choice of interesting hand-work, everything that is alive and responsive in them is released. The adult gives more—makes more imaginative effort to speak the child's language. Hence, the health enthusiast has a better opportunity to give out ideals to the active group in the play room than the nurse or the doctor dealing with the more or less awed and frightened individual child. It is true that the family physician has a far better chance to teach health than the clinic doctor. Knowing the child over a period of years he can become a sympathetic friend, whose advice and encouragement, whose opinion as to what is worth while in life, will be sought by the child. But the clinic director, with his brief touch-and-go contact with both mother and child is dependent upon the clinic "atmosphere," which alas, is dreary, or at least negative, where no effort is made to make it otherwise.

But to return to the health play room at the University of California, let me give briefly some simple devices used for teaching health. The

jig-saw can make small toys or useful objects for the child to take home; tops can be decorated with fruits and vegetables; napkin rings can be made in the form of Noah's Ark animals, decorated with such verses as the following:—

The cat, her hair
Is fine as silk
Because she always
Drinks her milk.

The duck is always
Neat and trim
Because he loves
To bathe and swim.

An unfailing source of interest is the making of original reading books. Children are given blank books and crayons and asked to illustrate and write about health habits. Amazing free hand drawings and reading matter that would astonish any public school teacher who had not tried this device are produced. The making of health posters always interests certain of the older children. The tiny youngsters are fascinated by the "Game of Healthland." With the help of the older children the sand box is transformed into the "map of Healthland" as given in the "Healthland Flyer" published by the Child Health Organization of America. Out of plastersene and colored card-board, Spinach Greens, Fruitvale, Long Sleep Mountain, and all the other towns are quickly reproduced. The younger children then operate the railroad running through Healthland, an inexpensive "wind-up" train with a generous supply of track. An older boy usually plays conductor, and calls out the stops, improvising many "specials" and "excursion" trips through Healthland.

There are other health games: "Cho-Cho's Health Game," a fascinating card game published by the Child

Health Organization; a panches-board with the "safetys" marked after the health habits, the final "home" marked "HEALTH," while the "don't" mark the "danger" zones. The old fashioned group games such as "Stage Coach" and "Packing the Trunk" can be amusingly adapted to interest the children in the different health foods.

One of the first requirements for successful health teaching in a clinic is a cheerful environment. No matter how cramped and make-shift the housing, walls and furnishings can always be painted in soft, pleasant colors. At the University of California clinic an effort is being made to have beautiful murals. Two wall spaces are already so decorated. Besides helping to create the right atmosphere, the children use the vegetables and fruits portrayed in these pictures as models for their work in plastersene. It is sometimes possible to secure such decoration through offering competitive prizes for the best murals to an art school, the successful students then putting their drawings on the walls, the clinic paying for the paint. Or friends of the clinic may raise funds to pay for the best artistic talent the community offers. Even where murals are not possible, do not let the house painter decide on your color scheme. An artist can always be found to make out a color scheme that will be pleasing to adults and children alike. In one instance where the house painter was the arbiter, the whole clinic was painted a horrible battle-ship grey, which chilled both adults and children.

Popular With Ward Children

At the University of California hospital it has been found most effective

and practical to introduce the health work in the wards.

In the afternoon, when there are few clinics, and the wards are comparatively free from doctors and treatments, the health director and her volunteer helpers work with the ward children, individually and in groups. After a child's interest has been aroused by some simple hand-work, there are many practical opportunities for the immediate practice of health habits.

How many have watched the trays with well chosen food—just right as to balance and calories—come down from the children's ward with only the dessert, or the potatoes, or the bread and butter eaten? The nourishing soups, milk, eggs, meat, cereals, green vegetables and fruits too often go begging. The nurse has no time, nor has she been instructed, to work with each child until he eats all his food, so that these children, who most need nourishment, get far less than the average child at home. Here is the health director's chance for some practical health teaching. Each child can keep an attractive chart of the day's menu, and the quantity eaten. The nurse's cooperation can be enlisted, and each child helped to fill out his chart before the trays are removed. The older children even enjoy roughly computing the number of calories they eat.

In how many hospitals do the children clean their teeth? The social service department could well make the purchase of the proper size tooth-brush and powder a requirement of entrance.

In this hospital, four bed units have taken the place of the large wards. This offers opportunity for group

competition, as an effort is made to assign the children according to age. Not only wholesome competition, but group achievement, is made possible by these smaller units.

Last year four room-mates, boys between the ages of ten and twelve, made a health marionette show, for which they wrote the lines.

Title: The stomach's strike.

Scene: A child's stomach—Time: Early in the morning.

Story: One night Johnny had received a present of money. Next morning before joining the home breakfast group he does some shopping on his own account at the corner store. A piece of chocolate cake, a banana, and a lollypop descend into his stomach. Later, when oatmeal and egg get a chance there is no room. That abused servant, the stomach, rebels. A strike ensues that only Doctor Castor Oil can quell.

The creation of this epic gave the keenest pleasure and amusement to these boys and afforded an approach to health that was the opposite of "preachy."

Every device that succeeds in the clinic is doubly valuable in the ward where more individual attention can be given, and where children often remain for weeks. The ward offers much greater opportunity for story telling, both by adults and children, reading of health stories, singing of health songs, and group games. The original health books and readers are of especial value in the ward as the child can keep blank book and crayons conveniently under the pillow, and so be able at all times to amuse himself.

One of the charming customs that has been established here is the celebration of birthdays. Whenever a child's birthday falls within the period of his hospital stay, a birthday party is given. The other children make

Traffic cop Cho Cho at entrance to Children's theatre demands that his health rules be learned.

Health teaching to the hospital wards interests the patients to eat the nourishing fare prepared.

simple presents, and all make paper caps to wear, decorated with fruits and vegetables. A special health song is usually composed in honor of the day. Last year the children even gave a surprise birthday party to Dr. Lucas, himself. They knew that he was dieting to keep down his weight, so they presented him with a large basket of shellaced fruits and vegetables as a decorative ornament for his office, a daily reminder to avoid the sinful carbohydrates. A many stanza song was composed for the occasion which expressed the children's revolt—and what they pictured must be Dr. Lucas' against health foods, sung to the tune of "Rufus, Rufus, etc."

Dr. Lucas, we've been thinking,
How much nicer it would be,
If all the spinach, it was growing
Far beyond the Northern Sea.

This is but one of the many instances that might be given to show the friendly and intimate spirit that creeps into the relationship between adults and children whenever health teaching is successfully carried out, whether in class-room, clinic, or ward. In the school the atmosphere of many a classroom has been transformed from the too tensely critical, or the coldly indifferent, to that of friendly human relationships under the kindly influence of the new health teaching. In the same way doctors and nurses find it easier to look upon small patients as individuals, instead of "cases" when the warmth, fun, and informality of health teaching have penetrated the clinic and ward.

Children who leave the wards very much under weight, and who have had

these happy contacts with the health director, can easily be persuaded to return weekly to the clinic for help in regaining normal weight.

One of the most interesting aspects of health teaching in the clinic and wards is the educational value of the work for medical students, nurses, and physicians. It may very well serve as a practical demonstration of the great need today for practical courses in psychology and pedagogy in medical and nursing schools.

And now you are asking how can this alchemy be set to work? Where do you catch your health director, and how do you interest and train volunteers for the work?

Dr. Lucas Originates Plan

At the University of California the plan for transforming the children's clinic into the Children's Health Theatre originated with Dr. William Palmer Lucas, professor of pediatrics, University of California medical school. Dr. Lucas had seen how marionettes can popularize health teaching at Lyons, France, while director of the children's work for the American Red Cross. When he learned that a Mrs. John Collier, assistant director of the Child Health Organization of America, was to make a demonstration of health teaching in the San Francisco schools, under the auspices of the San Francisco Tuberculosis Association, Dr. Lucas asked that the association also undertake a demonstration of health teaching in the children's clinics and wards of the University Hospital.

To carry out this plan the Women's

Auxiliary of the University of California Hospital provided the full time services of a trained recreational leader, Helen Crawford of Henry Street Settlement, New York. Miss Crawford not only developed the health education work, but organized a group of some sixty volunteers to take part in all the usual volunteer services, including some therapeutic work with adults. Mrs. Collier provided the health methods and devices that have succeeded in the class-room work, and Miss Crawford transplanted these in terms of the various handicrafts practicable for hospital use. Volunteers, who are by temperament fitted to work with children, soon become skillful in popularizing health teaching. When Miss Crawford had to give up the work, after nine months, a clever young school teacher was found who carried on the work admirably.

The following literature will be found of use in first organizing health education work in a clinic: Health Education Series, U. S. Bureau of Education including: Suggestions for a Program for Health Teaching in Elementary Schools, Diet for the School Child, Milk and Our School Children, and Further Steps in Health Teaching. Those suitable to read aloud: Child Health Alphabet, Cho-Cho and the Health Fairy, Rosy Cheeks and Strong Heart, Rhymes of Cho-Cho's Grandma, Miss Jenkins' Sketch Book, Many Roads to Health.

Helpful Child Health Organization literature includes: Healthland Flyer, Healthland Map, Happy's Vanity Case.

Levi Memorial Hospital Treats 5,000 Yearly

Clinics supplement the hospital service

Leo N. Levi, Memorial Hospital, Hot Springs, Ark., maintained by B'nai B'rith, has in its seven years' experience treated 2,609 patients in the hospital proper and 13,000 in its clinics. During the past year 5,000 persons, 740 in the hospital and 4,000

in its clinics, received treatment.

The plant consists of a three story main hospital with well equipped laboratories. Its most urgent need is a nurses' home for which the order hopes to raise \$25,000. A plot 150x150 adjoining the hospital has been

given by the United States government for the erection of such a home.

The hospital treats only serious and obstinate cases which will be benefited by use of Springs waters. It is maintained by the B'nai B'rith order for its sick poor.

The Possibility of Extending Human Life*

BY LOUIS I. DUBLIN, Ph.D., STATISTICIAN, METROPOLITAN LIFE INSURANCE COMPANY, NEW YORK CITY.

THE subject under consideration has been a favorite one for speculation from the earliest antiquity up to our own time. The poets, prophets and philosophers have all been concerned with it. But, unfortunately, they have approached the subject with a bias. They have permitted their personal desire for extended life to determine their thought. In our own time, Shaw has given dramatic treatment to the subject, but he has approached it like the rest and has assumed that mere wishing can be converted into actual accomplishment. We will not approach the subject from that angle. We are concerned primarily with the facts. We are more fortunate than our predecessors. We have a body of knowledge which they lacked and, what is more important, a scientific method of analysis. We shall not say arbitrarily with the Psalmist, "The days of our years are three score and ten." We shall rather ask and attempt to answer a series of questions such as: "What are the conditions of health and mortality which determine the life span?" "What is the present duration of human life?" "How does that vary from place to place and from group to group?" "How much has it increased in various periods of time and what elements have led to the increase?" Finally, "How much more is there still ahead of us?" In such an approach, it is hoped there will be no room for dogmatism and no pretense to finality. We shall be humble seekers for the

"What are the possibilities of extending human life? This question can have meaning only as it has reference to the present state of our knowledge of preventive medicine and applied sanitary science and to the present levels of human well-being. It would be futile for us to prognosticate on the basis of any substantial future advances in medical, surgical, or sanitary knowledge, certain as we may well be that important advances will be made and within a reasonably short time. We are, therefore, virtually compelled, in seeking an answer to our question, to piece together a picture of an attainable mortality experience out of the best experience that now exists. There can be no complaint of undue optimism when we rest our case upon actual achievements or what is on the threshold of achievement."

truth wherever that may lead us.

Obviously, the first step in our discussion is to discover a yardstick or measure of the human life span. No scientific discussion of the subject is possible without that. The first measure we have is one with which you are familiar, namely, the death rate. You know, for example, that the death rate of New York City last year was 11.17 per 1,000. This means that there occurred in that year ap-

proximately 11 deaths for each 1,000 of the population, or 112 deaths per 10,000 of the population, or, as we sometimes say, 1,117 deaths per 100,000 of the population. This figure is obviously a rough measure and tells us little or nothing with regard to the longevity of the people of the city. We immediately get into difficulties with this rate when we begin to compare the mortality of New York City with that, say, of Seattle, Washington, where the rate is lower. The fact is, that the populations of New York City and of Seattle are not constituted exactly alike as to the proportion of young and old people, and in other respects. If, for example, there are more babies and more old folks proportionately in New York City than there are in Seattle, that alone will materially increase the total death rate of New York City because it is among the babies and old people that mortality is heavy. This is universally recognized and, instead of the crude death rate for the whole population, we proceed to prepare death rates for specific age divisions of the population as well as for the whole. There is, for example, what we call the infant mortality rate. This means the death rate in the first year of life. We calculate, also, the death rates for the period of pre-school life, for other ages of childhood, for the broad span of early adult life, then of middle life and old age. These values give us a measure of mortality for each age division of life, and may be compared for various places. The finer the subdivision of age, the more precise becomes comparison of mortality.

*An address delivered before the Harvey Society of New York, at the New York Academy of Medicine, December 16, 1922.

The life table is not as complex as it appears to be. As a means of measuring the life span it is essentially accurate, is simple in construction, once the graduated rates of mortality are obtained, and produces figures for various places and various groups of people which are comparable. It is usually difficult to compare the health conditions of different countries or even of different cities in the same country by comparing their death rates, because of the varieties of age constitution of the people in the several places or because of so many other conditioning factors which affect the death rates. The life table irons out these differences. It applies the actual facts of mortality for the whole span of life and, later, gives the resulting values of expected longevity for the average individual of the group.

Comparative Longevity

Let us become familiar with some of the very obvious facts of longevity at the present time. The expectation of life at birth for the entire population was nearly 51.5 years in 1910.

TABLE 1.—COMPLETE EXPECTATION OF LIFE AT SPECIFIED AGES—MALES AND FEMALES AND BOTH SEXES IN UNITED STATES ORIGINAL REGISTRATION STATES, 1910.

Age	Both Sexes	Males	Females
0	51.49	49.86	53.24
1	57.11	55.94	58.37
2	57.72	56.59	58.94
3	57.44	56.33	58.63
4	56.89	55.79	58.08
5	56.21	55.11	57.39
10	52.15	51.07	53.31
20	45.53	42.48	44.66
30	35.70	34.70	36.79
40	28.20	27.32	29.15
50	20.98	20.32	21.67
60	14.42	13.95	14.90
70	9.11	8.83	9.38
80	5.25	5.10	5.37
90	3.03	3.01	3.05
100	1.55	1.81	1.91

(Table 1). The maximum expectation occurs in the third year when it is 57.72 years; that is because the child of three has already overcome the heavy initial mortality in the first two years of life. Even at age 10, the expectation is greater than at birth and for the same reason. But, from this age onward, the expectation declines regularly with every advancing year of life. At 25, the expectation in 1910 was 39.6 years; at 40, 28.2 years; at 50, nearly 21 years. That means that persons surviving to age 50 may, on the average, expect to survive to age 71. Some, of course, will die in their fiftieth year and some

may be centenarians. But the average individual at 50, if we may conjure up such an imaginary person, may, with reason, expect to live to

more than two years greater; at 50, it is a year and one-third greater; and at 70, about one-half year greater.

Chart 1.—Shows how the duration of life varies from place to place in the civilized world.

age 71; or, as we put it, the average length of life remaining to each one of the survivors at age 50, is 21 more years. Even at 70, there are still more than nine years of expectation and so on in a diminishing degree to the end.

Sex is a very important element in mortality. You know that the mortality of women is less than that of men. Their expectation of life is, therefore, greater. The life table for the two sexes tells us how much greater. Table 1 also shows the facts for the original Registration States in 1910, at selected ages, for males on the one hand, and for females on the other. The females have an expectation at birth three and one-third years greater than for males; at 30, it is

Table 2 and Chart I show how the duration of life varies from place to place in the civilized world, reflecting the varieties of health standards and of well-being prevailing in the various countries.

New Zealand shows the greatest expectation of any of the countries listed. For males, the complete expectation was 59.2 years at birth, as compared with 49.3 in the United States. The Australian figures follow next in order of excellence. The Scandinavian countries, Denmark, Norway and Sweden, are very close to Australia in the length of the life span. The conditions of England and Wales approximate those in the United States. France, Germany, Italy and Japan are a few years below the United States

TABLE 2.—COMPLETE EXPECTATION OF LIFE AT SPECIFIED AGES—VARIOUS COUNTRIES IN RECENT YEARS

Country	Year	Males				Females			
		0	30	50	70	0	30	50	70
Australia	1901-1910	55.20	36.52	21.16	8.67	58.84	39.33	23.69	9.96

Holland	1900-1909	51.00	37.80	21.80	8.90	53.40	38.50	22.90	9.40
India	1901-1910	22.59	22.44	13.97	6.17	23.31	22.99	14.28	6.22
Italy	1901-1910	44.24	35.94	20.73	8.02	44.83	36.53	21.47	8.02
Japan	1898-1903	43.97	33.44	18.97	7.89	44.85	34.84	21.11	8.77
New Zealand	1906-1910	59.17	38.78	22.67	9.38	61.76	40.45	24.30	10.31
Sweden	1901-1910	54.84	38.86	23.96	10.57	57.72	40.24	25.31	11.23
Norway	1901-1910	54.53	38.57	23.17	9.85	56.98	40.20	24.74	10.63
Switzerland	1901-1910	49.25	38.80	18.90	7.78	52.15	36.10	20.71	8.15
United States	1901-1910	49.32	34.80	20.59	8.96	52.54	36.75	21.86	9.52

in the average duration of life. In India the life span is only about one-half of what it is in European countries. The important point to remember is the great diversity in the span of life in the various countries, ranging from 61.8 years for females in New Zealand to 22.6 years for males in India. You will realize why these differences occur in the light of the sanitary, social and economic conditions that prevail in the various parts of the world. You will understand also why the people of some countries enjoy great prosperity and a larger measure of well-being while those in others are always near or under the line of distress and general misery.

Increase in Longevity

A substantial increase in the life expectation has occurred in the last century. (Table 3.) This fact is the best indication we have of the greatly improved material progress of the great mass of people in the civilized countries of the world. The figures for England and Wales are the most instructive for our purpose. The first life table for the population of that country described the period between 1838 and 1854. The average length of life was then nearly 41 years. A series of life tables follows the first and shows a successive gain from decade to decade. The seventh table, that for 1910 to 1912, gives an average expectation of nearly fifty-three and one-half years. There has, therefore, been a gain in the interval of seven decades of twelve and a half years. On the Continent, the best historical data are for Sweden. A table for the years 1816 to 1840 shows expectations of forty-one and one-half years. The last table (1901 to 1910), gives fifty-five and three-quarter years. These are gains of fourteen and a quarter years in the interval of eight decades. In our own country, the first table of any value is for Massachusetts (1855). The values agreed essentially with those for England and Wales for the corresponding period, the life expectation in both Massachusetts and in England and Wales being about forty years. In 1910, the Massachusetts figure had increased to fifty-one years, showing a gain of eleven years in the half century. In 1920, the figure was over fifty-five years or a gain of more than fifteen years in sixty-five calendar years. In the Registration States of the United States, we find an increase of six years between 1901 and 1920.

There is another and perhaps better way to see how great has been the improvement in the life span in

TABLE 3.—EXPECTATION OF LIFE AT BIRTH, PRINCIPAL COUNTRIES OR STATES AT VARIOUS TIMES

the last century or so. That is, to observe the age at which the original number of our life table population,

100,000, is reduced by one-quarter, one-half and three-quarters. Table 4 and Chart II show the facts for Eng-

Chart 2.—Shows the facts for England at the time of first and last tables and for New Zealand at the time of this last table.

land at the time of the first and last tables and for New Zealand at the time of its last table.

The same life tables also lend themselves to another interpretation. In

bring the largest proportion of its people up to the threshold of old age.

Possibly, the most encouraging results have been obtained among insured lives, where a definite effort has

pectation of life at age ten among the four classes of insured persons (white male, white females, colored males and colored females.)

The significant thing about this insurance experience is the light that it throws on the possibilities of further life extension. The mortality rate and the corresponding average after-life-time respond very quickly and favorably to intelligent effort. The same thing has happened in the general population of the United States and in the European countries whose figures we have quoted, but the response has been less pronounced, probably because conservation work was applied less exactly and less intensively. The lesson is forcibly brought home that we are still far from having attained the maximum possibilities in the extension of human life under present conditions in any group among whom the experiment has yet been tried.

Possibilities of Future

What, then, are the possibilities of extending human life? This question can have meaning only as it has reference to the present state of our knowledge of preventive medicine and applied sanitary science and to the present levels of human well-being. It would be futile for us to prognosticate on the basis of any substantial future advances in medical, surgical or sanitary knowledge, certain as we may well be that important advances will be made and within a reasonably short time. We are, therefore, virtually compelled, in seeking an answer to our question, to piece together a picture of an attainable mortality experience out of the best experience that now exists. There can be no complaint of undue optimism when we rest our case upon actual achievements or what is on the threshold of achievement. This, then, is our assumption. Let us see what that leads to in the actual working out of our case.

The most important single item of mortality is the record for the first year of life. Fifteen per cent of all the deaths that occur each year are of children within the first year of age. Infant mortality cuts very heavily into the life expectation because a death in that year erases the entire expectation for that life, whereas a death at a later age, say forty or sixty, removes only relatively few years of life, and, as a result, the effect on the average is slight. Fortunately, there is compensation for high infant mortality, namely, its relative ease of prevention and control. In the Birth Registration Area

TABLE 4.

Country	Date of Life Table	AGE IN WHICH THE ORIGINAL NUMBER OF A GENERATION IS REDUCED BY—					
		One-Fourth		One-Half		Three-Fourths	
		Males	Females	Males	Females	Males	Females
England	1838-1854	3.25	5.00	44.33	46.33	68.17	70.08
	1910-1912	33.25	40.00	61.33	65.67	78.83	77.08
New Zealand	1906-1910	48.33	51.50	68.00	70.50	77.83	79.83

England, at the time of the first table, only 29.5 per cent of the male and 32.4 per cent of the female population attained age 65, whereas at the time of the last table 43.5 per cent of the males and 51.2 per cent of the females attained that age. In New Zealand, where the best longevity conditions prevail, 55.9 per cent of males and 60.5 per cent of females reached the age of 65 in the period 1906 to 1910. As this is the age which closes the active working period of life, it must be obvious that that nation is the most productive, and its people enjoy the largest measures of longevity, and shall I add prosperity, which can

been made to extend the life span. In 1909, the Metropolitan Life Insurance Company began an active campaign of health education among its millions of industrial policy-holders. This was supplemented with the development of nursing care for those who were acutely ill. The death rate during this period showed continuous improvement, dropping about one-third in the decade. Accompanying this drop in the death rate, there was an increase of eight and one-half years in the expectation at birth for these insured lives representing the working population of America.

Chart III shows the gains in ex-

Gain in Expectation of Life at Age 10

Wage Earners Insured in
Metropolitan Life Insurance Company
1921, 1919-1920 and 1911-1912 Compared

Chart 3.—Shows the gains in expectation of life at age 10 among the four classes of insured persons.

of the United States, the infant mortality rate dropped in 1921 to 76 per 1,000 births. In New Zealand, in 1920, it was below 50 per 1,000 births for the entire country, and there are a large number of cities in the United States, some of good size, where the infant mortality at the present time is below 40 per 1,000 births. We have accordingly started our hypothetical life table with the basic assumption that an infant mortality rate of 38.2 expresses an entirely realizable figure under present conditions, although it is only a third as great as that in the 1910 Life Tables, which we have just examined. Do not be unduly disturbed by what looks like a very radical assumption of too low infant mortality rate. It really is not at all extreme. If anything, it leans over to the side of conservatism, because the assumed value has not only been attained in any number of places, but there is every indication that it is attainable by the whole country within a relatively short period of years. We can, in fact, surpass it by paying attention to one particular, namely, the suppression of the infant mortality of the first month in which hardly anything has as yet been achieved on a country-wide scale. In another place,¹ the author has recently outlined a procedure which will do for early mortality what the general baby welfare movement of the last twenty years has accomplished for children above the first month. The detection and handling of syphilis in the mother, the control of the toxemias of pregnancy, and the provision of good obstetrics for the great body of parturient women, coupled with the type of nursing care now largely available in the cities of the United States, will give us what we hope for. This favorable level of the infant mortality rate has been amply demonstrated as attainable. Infant mortality rates of 20 per 1,000 births and even below that are on the horizon. We have assumed a higher rate of 38.

In like manner, we have proceeded on the general assumption that the mortality in the succeeding four years of childhood is materially reducible. Our assumed figures for the second, third, fourth and fifth years vary between 34 and 40 per cent of the actual mortality rates for the respective ages in 1910. Each one of the values was determined with the greatest care, having in mind the rates prevailing in the most favored countries, and what we know can be done to pre-

vent mortality from the diseases and conditions of the pre-school years. Thus, we have assumed a mortality rate of 4.2 per 1,000 for the third year of life. In New Zealand, nearly fifteen years ago, the rate was 5.3. Our figure is only 20 per cent below the relatively remote New Zealand figure. In the third year of life virtually two-thirds of the entire mortality is due to such infections as typhoid fever, diarrhea and enteritis, the four communicable diseases of childhood—measles, scarlet fever, whooping cough and diphtheria—tuberculosis and the respiratory diseases. Who will deny that these conditions are now within control, provided we mean to control them? How great is the promise for the eradication of diphtheria through the general application of methods now employed in this very city, *viz.*, that of wholesale inoculation of children with toxin-antitoxin? Yet, diphtheria looms large in the mortality not only in the third year of life, but in all of the years of childhood after the first.

Between the ages of ten and sixty, in that broad fifty-year span of life, we have made one basic assumption throughout, namely, that mortality can be reduced to one-half of the figure which prevailed in 1910. This is an important point in the procedure of building up our hypothetical life table. Between ages five and ten, the values were interpolated so as to give a smooth juncture between ages three, four and five and the ages after ten. It meant graduating the values from 40 per cent of the 1910 mortality at age five to 50 per cent of the 1910 figure at age ten. At age ten, we used a death rate of 1.1 per 1,000; the New Zealand value was 1.4. The vital item in our procedure was, however, the assumption that in the age range covering virtually the entire active period of life from ten to sixty, the mortality is capable of a 50 per cent reduction from the 1910 figure. Again, our values are, for the most part, only 20 per cent below those for New Zealand in recent years. But, in that country, as in our own, there is still much preventable mortality from tuberculosis in the working period of life. There is also the serious mortality from occupational and other accidents. In the latter part of this broad age period, there is already a heavy death rate from the diseases of the heart, kidney and blood vessels, much of which is preventable and has actually been prevented or postponed in limited groups of the population.

Our assumed rates between ten and sixty are, moreover, very close to

those attained by the best life insurance companies in their current Ordinary experience. At some of the ages, the actual insurance experience is even lower than the values we have assumed. We in the life insurance business are more and more impressed with the splendid possibilities before us for the further curtailment of mortality among insured persons. Through such procedures as the annual physical examination and the hygienic follow-up to encourage the insured to bring their impairments under medical supervision, we hope to attain large results. An investigation into the mortality of a group of Ordinary policy-holders of the Metropolitan who had availed themselves of the privilege of the Life Extension Institute examinations over five years ago showed at the end of the period a mortality 28 per cent lower than that of the best control group we could muster, having in mind all the logical requirements of the comparison.

We are especially optimistic as to the future because of the amazing reduction in the death rate from tuberculosis which is occurring throughout the world. Since 1911, the disease has declined 50 per cent among those insured in the Metropolitan and almost as much in the general population of a number of progressive cities. The disease is not only declining rapidly in actual mortality, but the peak or maximum rate by age is constantly being pushed forward into the later years of life. This has the effect of extending the expectation. On the other hand, we are not doing so well with reference to the diseases and conditions which reflect personal hygiene and the general care and use of the human body. The death rates from the so-called degenerative diseases, like heart disease, Bright's disease, cerebral hemorrhage and the other diseases affecting middle life and the older ages are not declining. We are making little headway in spite of increasing public and medical interest in them. These deaths represent heavy losses to the community because they involve in many instances people still in their prime and at the height of their usefulness. The development of a well-conceived campaign against these losses, organized along lines which have proved successful against tuberculosis, will, according to the best medical opinion, produce excellent results. Together, the three diseases—heart disease, Bright's disease and cerebral hemorrhage—curtail the expectation by about four years. A further reduction in the in-

1. "The Mortality of Early Infancy." Read before the Thirteenth Annual Meeting of the American Child Hygiene Association, October 13, 1922, Washington, D. C.

cidence of the acute infectious diseases, such as typhoid fever, diphtheria and acute rheumatism, which are so fruitful in producing damage to the heart, kidneys and vascular systems of young people, will bring important results, as will also the extension of health education and the inculcation of better health practices among adults. It is reasonable to expect that an appreciable part of the 50 per cent mortality reduction postulated by our hypothetical life table will be accomplished through these means.

The further extension and the more intensive application of the life-saving campaign to industry likewise holds out much promise. The prevention of occupational mortality has scarcely been begun as a nation-wide effort. There can be no question that certain industrial processes widely developed throughout the country seriously shorten the life span. The effects of excessive heat, of poisonous fumes, of deleterious dusts and actual contact with poisonous substances, unduly long hours of labor, all result in raising the mortality rate of industrial workers far above those for the general population. The excellent physical endowment of industrial workers assures a greater life expectation under conditions of improved industrial hygiene than is actually attained at the present time. Occupational accidents alone are still responsible in the United States each year for as much as fifteen thousand deaths, for the most part of men in their prime. Employers of labor can give material aid in the campaign to reduce adult mortality in America one-half. The ever-growing interest of employers in safety measures and in shop sanitation gives much encouragement for the future.

Please notice that we have limited ourselves to those possibilities of life saving which are reasonably likely to occur on the basis of past experience. We have made no allowance for any possible saving from cancer, for example, because it would evidently involve more knowledge than we now have of the causative factors of this disease. In like manner, we have made no assumption of life saving in old age, that is from, say, age 70 onward, because during the last half century there has been practically no improvement in the mortality among aged persons. The only liberty we have taken in the preparation of our hypothetical life table is to graduate the mortality values from 50 per cent of the actual in 1910 at age 60 to 100 per cent mortality at age 70. This

provides a smooth and reasonable transition from a period where life extension is still somewhat possible to one where no substantial gains are at present in sight.

This hypothetical life table (Table 5) expresses the best mortality we may hope for with our present knowledge and in the light of our actual achievements. The total expectation of life at birth is 64.75 years; or, for the purposes of easy reference, let us say, 65 years. This means an addition of ten years to the life span now prevailing in the United States which, as we have seen, is only 55 years. Notice that there is no sharp rise in the table after the first year of life, as there was in the earlier life tables. That is because we have reduced the infant and child mortality to a third of the previous figure. According to our new table, a person of 20, that is, one who is about to enter active adult life, would have an average expectation of 50 years of after-

TABLE 5.—HYPOTHETICAL LIFE TABLE

Age	Number Living in Specified Age Interval	Mortality Rate per 1,000	Expectation of Life

Note.—Constructed from Life Table for United States Registration States, 1910, on following assumptions as to mortality rates:

Age	Assumed Reduction from 1910 Rates
0 to 5	Approximately two-thirds
5 to 10	Two-thirds to one-half
10 to 60	One-half
60 to 70	One-half to no reduction
70 and over	No reduction

lifetime. That means that those crossing the threshold of manhood and

Comparison of Survivors and of Complete Expectation of Life.
Life Tables for U.S. Registration States, 1910 and 1920
and for Hypothetical Life Table

Chart 4.—Shows difference between old rates and expected improvement. The greater part of the gain is limited to early life.

womanhood may expect, on the average, to attain age 70. What a curious confirmation our figures give to the biblical allotment of three score and ten!

A comparison of our hypothetical life table with the expectation prevailing in the Registration States in 1920 indicates a possible gain of ten years at birth; of fully five and one-half years at age 20; of three and a quarter years at age 40; of two and one-half years at age 50; and of one and one-third years at 60; at 70 and thereafter there is no gain to be expected because no improvement in the mortality rates was assumed in the construction of the table. The greater part of the gain is obviously limited to early life, where there is still the greatest opportunity for preventing mortality. But the possible gains in middle life are sufficiently large to justify every effort in their attainment. (Chart IV.)

How great these gains would actually be is shown by comparing the number of deaths now occurring in the United States each year with those which would occur under the death rates called for by our Hypothetical Life Table. The total death rate would be reduced from 13.0 to 8.6 per 1,000, assuming no change whatever in the age constitution of the present population. In other words, an extension of the expectation by ten years in accordance with the suppositions of our Life Table would be accomplished by a coincident reduction in the death rate of 33.8 per cent. On the new Life Table basis, there would be a total of close to 916,000 deaths in the United States as against a total of approximately 1,379,000 which occurred in 1920, or equivalent to a saving of 463,000 lives a year. The greatest saving would be accomplished in the first year of life. A reduction of the infant mortality to a third as assumed by us means a saving of 126,000 infants a year. In fact, the saving would be 171,000 children in the first five years of life. The saving, on our assumption of one-half mortality between the ages 10 to 60, is equivalent to a reduction of 250,000 in the number of deaths in that age period. These large figures show very strikingly how great are the stakes involved in the program of life-saving implied by the Hypothetical Life Table we have constructed. It is very encouraging in this discussion to remember that these savings are just as reasonable as are the assumptions of reduced mortality whose plausibility we have defended in our previous sections.

Possibly, in assuming virtually no improvement after the close of active life, the author has opened himself to serious criticism. There are those who on plausible grounds see much improvement in mortality at the older ages as a possibility for the future. They are much impressed with the large results being obtained in small groups through emphasizing more intensive personal hygiene. They are not over-impressed with the fact that the last half century has shown no response at the older ages to the improved conditions of life. They profess to see that much of the mortality from the so-called degenerative diseases that prevails at the older ages can be curtailed by preventing the infectious diseases of early life, and by more reasonable and intelligent conduct of our personal lives. All of this seems very reasonable and I should regret very much if it were assumed from what I have presented that the span of human life is practically fixed and that no material extension of it can be expected beyond

the average of sixty-five indicated by my life table. The figure that we have presented is simply a summary of what we believe to be the most probable figure, having in mind the present state of our knowledge. It is entirely conceivable that a medical discovery of the first order which would do for, let us say, chronic nephritis, what the newer therapy has accomplished for syphilis, or what promises to be accomplished for diabetes, would add somewhat to our maximum figure. The additional gain would not be very much because the saving would be at the advanced ages when the expectation is low by comparison. All of this, however, is for the future and it would be idle for us to dwell at this time on such possibilities.

The twelfth annual National Safety Congress will be held at Buffalo, October 1 to 5, 1923, according to an announcement by W. H. Cameron, managing director for the executive committee of the Council.

Discovery of the Influenza Germ

Copr. Life Publishing Co.
How *Life* depicts the recent dénouement of the still hunt for the influenza germ which has been going on since the epidemic conditions of 1918.

Newspapers have made much of the announcement that the admirable experiments of Olitsky and Gates of the Rockefeller Institute have resulted in the isolation and cultivation from the nasal secretions of influenza patients of an organism so minute that it can pass through a filter, and which, when injected into the windpipe of the rabbit, produces in the animals' lungs conditions like those found in the lungs of human subjects of influenza.

The second generation of the organism produced typical attacks of influenza in a human subject whose nose and throat were sprayed. Noting the fact that Olitsky and Gates could get no growth of their organism from the secretions of eight persons suffering from "acute coryza," the ordinary cold, *Health* points out that one result of the discovery will be a much better discrimination in the use of the term influenza which has heretofore had too wide a connotation.

Study of Visiting Nurses

THE committee to study visiting nurses instituted by the National Organization for Public Health Nursing, completed the study of nursing in twelve cities, by January, 1923. The survey under the direction of the chairman, William F. Snow, M. D., was carried on by an accountant, or nurse investigator, or both.

Organizations studied were the Visiting Nurse Society, Philadelphia, on which the plan of study was first tried out, Public Health Nursing Association, Rochester, N. Y., Visiting Nurse Associations in Cleveland, Omaha, York, Pa., Denver and Louisville, Ky., Cherokee County Public Health Service, Kansas, Public Health Nursing Service, Oklahoma City, Okla., Bureau of Municipal Nursing, Department of Health, Los Angeles, Child Welfare Association, New Orleans, and rural work of Charlotte Cooperative Nursing Association, Mecklenburg County, North Carolina.

Additional associations are now being studied.

The general aim and plan of the committee is by studying the visiting nursing services in a sufficient number of specified centers, probably not less than 15, to evaluate the present quality of visiting nurse work and determine the "per visit cost."

The committee will recommend the content of the various types of visits made by visiting nurses; the most economical operating machinery necessary for making such visits; this to include quality of the workers, quantity, quality and character of supervision, relation of cost of time spent in travel, record keeping, and administration to that spent on nursing; a uniform system of accounting for use by visiting nurse associations and a basis for determining the "per visit cost."

The procedure of the committee is to gather material on the present practice of visiting nursing in a number of public health nursing agencies. These data will later be studied by the committee and will form the basis for their recommendations.

The general phases of public health nursing to be observed in each association involve a detailed schedule covering the facts of organization and administration will be filled in for each association by one of the nurse investigators. This schedule covers necessary details on the following points: For the city, population,

area, death rates, causes of death for last fiscal year; for the association, organization, board and committees; personnel, paid workers, students, substitutes, volunteers; administration, training new workers, conferences and other educational methods, supervision, record writing, hours, uniforms, transportation, publicity, quarters, policy regarding giving of relief; type of work, general visiting nursing, specialized service, general policy and type of service for each type of case; analysis of statistical material for last fiscal year, number of patients, number and classification of visits, diagnoses of patients, fees, sources of patients; information on cooperation or overlapping of service with other public health nursing agencies in the community and with other social agencies.

In addition to this information on organization and administration the nurse investigator is also obtaining first hand a knowledge of the nursing technic and type of records kept. In each association she is spending a day in the field with each of a carefully selected number of nurses. For each visit with each nurse she fills in a uniform schedule which gives a picture of that particular situation and the way it was handled. In each association she is also reading a uniformly selected sample of records and for

each record read fills in a schedule which will form the basis for a comparative evaluation of the content and use of records.

To supplement the information contained in the above schedules, each association is having all staff nurses keep a duplicate copy of their daily report sheets for a week. This material will afford a valuable basis for analysis of time involved in different types of visits, in transportation and in record writing and clerical work.

The staff members of the associations studied are also filling in personnel sheets which give educational background, professional training, previous experience, position on the staff and salary.

The investigators appointed to assist the committee in this study are: director of investigation, Almena Dawley; nurse investigators, Janet M. Geister, Theresa Kraker; accountants, Walter F. Derry, Lefa Nay.

The Henry Phipps Institute, Philadelphia, is sending out radio talks on health subjects every Tuesday evening. Dr. Charles J. Hatfield, executive director of the Institute, gave the first lecture with a preliminary address by Mrs. Arthur M. Dannenburg. Scheduled for future lectures are Dr. H. R. M. Landis, Dr. George Fetterolf, Dr. James M. Anders, Dr. George Morris Piersol, Dr. Samuel McClintock Hamill, and Dr. David Riesman.

Bertillon Methods for Sanitary Inspectors

Bertillon methods are now being used by the health department of Washington, D. C., in the collection of evidence of violation of sanitary laws. The photograph shows a physician and chemist in the Washington health office viewing paper cups which show clearly that they have been used twice by the soft drink establishment from which they were obtained.

Medical Social Service and the Physician

BY JACOB A. GOLDBERG, A.M., PH.D., DIRECTOR, COMMITTEE FOR HEALTH SERVICE AMONG JEWS, NEW YORK CITY.

MEDICAL social service dates back to 1905, when Dr. Richard C. Cabot organized the first medical social service department in this country in the out-patient department of the Massachusetts General Hospital. The reasons for the organization of this new branch of work were that the physician treating a patient could become acquainted with only certain phases of the mental and physical condition of the patient, and it was necessary to call in the trained social service worker to assist him in making a more accurate diagnosis and in rendering the prescribed treatment more effective. This new form of service was at first designed primarily for those who came to the out-patient department of the hospital. Since then the movement has spread to many of the general and other hospitals in the country, and the social service departments now serve both the ward and dispensary patients.

In every community there are large numbers of wage-earners and salaried people who prefer to go to the private office of a physician rather than to a dispensary. Also, there are those who for one reason or another enter private hospitals which do not maintain social service departments. Thus far, medical social service has not been extended to these groups of patients.

A clear understanding of this phase of the problem of treating the sick may be obtained from a consideration of the following statistics. According to the Medical Directory published by the Medical Society of the State of New York, there were, in 1921, 8,769 physicians in Greater New York, with 5,184 in Manhattan, 784 in the Bronx, 2,389 in Brooklyn, 324 in Queens, and 88 in Richmond. A study of the number of physicians on the staffs of hospitals, dispensaries, and clinics, has shown that in 1921 there were approximately four thousand one hundred physicians with such affiliations. It should further be noted that not more than two-thirds of all hospitals, dispensaries, and clinics in the city maintain social service departments and, when they do, these departments are usually for the exclusive service to the patients attending them. The effectiveness of the various hospital social service departments varies considerably, depending

upon the importance placed upon medical social service by the lay and medical boards; the training and experience of those in charge, and of their assistants; the funds available, etc.

The doors of social service departments are closed to all who seek and to those who render private medical service. Partially to meet this problem, the Committee for Health Service among Jews has advised physicians in Manhattan and the Bronx that the Committee is ready to serve as the medical social service agent and clearing house for their private patients in need of some form of medical social service. The monthly bulletin of the Eastern Medical Society contains the following notice. Similar notices have been mailed to members of other medical societies through the cooperation of the officers of these societies.

SOCIAL SERVICE FOR PRIVATE PATIENTS

Medical Social Service is today considered a most necessary element in hospital organization. Heretofore this form of service has been limited to those who were patients in hospitals. It has not been made available for private patients, especially for those under the care of physicians unaffiliated with hospitals. IF YOU HAVE PATIENTS IN NEED OF SOCIAL SERVICE OR ADVISE ALONG THOSE LINES, GIVE YOUR PATIENTS A LETTER TO: DR. JACOB A. GOLDBERG, Director Committee for Health Service among Jews, 356 Second Ave., N. Y. C. Absolutely no charge will be made to you or to your patient for this service. A written report of the action taken will be sent to you in every case.

Physicians have readily availed themselves of the services of the Committee. Within a few months, approximately two hundred patients have been referred for some form of service. It is expected that as the technic of this work is more fully developed and physicians come clearly to understand the nature of the cooperation offered, that a growing number of patients in need of some service will be referred for a study of their problems and the making of such social and other adjustments as may be found possible and necessary.

An adequate picture of the services rendered can best be portrayed by the citation of typical cases, as well as by an analysis of at least one hundred patients, their social and medical problems, the reasons for which they

were referred and how their problems were met.

Case 1.—Dr. S. referred Mrs. B. for convalescent care following an operation for appendicitis. Acting upon the diagnosis and recommendation of the physician, application for the patient was filed with a convalescent home, where patient was admitted within a few days.

Case 2.—Dr. W. referred a young woman of 19, suffering with pulmonary tuberculosis, the need being institutional care. Through one of the affiliated organizations of the Committee, the recommendation of the physician was fulfilled.

Case 3.—Dr. M. referred a young woman for the placing of her one year old infant in a boarding home. The husband had deserted and the wife wanted to return to the work she had been engaged in before her marriage. A suitable home was found for the infant.

Case 4.—Dr. A. referred a sixteen year old cardiac boy for institutional care. Members of the family were able and willing to pay for them, and arrangements were made for his admission to an institution for cardiacs.

Case 5.—Dr. F. sent an eighteen year old boy to the office of the Committee because he could neither get along at home nor at work. Upon examination by a psychiatrist, the boy was found to be a case of dementia praecox and he was placed under the care of a mental hygiene clinic and psychiatric social worker.

These cases are typical instances in which service was rendered to patients under the private care of a physician. An analysis of one hundred consecutive cases referred by sixty physicians for some form of service indicates a comparatively wide range of diagnosis.

Anxiety neurosis.	1	Indolent ulcer	1
Asthma	2	Locomotor ataxia.	1
Anemia	2	Lues, cerebro-spinal	1
Arteriosclerosis	1	Manic dep. inst.	2
Arthritis	1	Neurasthenia	12
Cardiac	12	Orthopedic	2
Carcinoma	4	Paralysis agitans.	1
Conjunctivitis	1	Paralysis, facial.	1
Dementia praecox.	3	Pneumonia	2
Duodenal ulcer.	1	Scurvy	1
Epilepsy	2	Syphilis	2
Gangrene of leg	1	Tuberculosis	14
General debility	19	Negative	5
General paralysis.	1		
Hemiplegia	2	Total	100

Cardiacs, general debility, neurasthenia and tuberculosis, stand out among the conditions found, their total being 57 per cent. This is probably indicative of the kind of cases in which physicians frequently need other than medical services to treat their patients, and to bring them to a state of physical and mental well-being as well as economic independence. Even though physicians generally realize the problems with which their

patients are faced in trying to adjust or readjust their lives to meet the accidents of sickness and death, they cannot in many instances help them because of an inadequate knowledge of the social agencies, their functions, etc., in the community in which they live. There are certain alternatives open to the physician in such cases. He can try to acquaint himself with the social agencies in his city and make his personal contacts with the executives and others; he can, as some physicians have already done, engage a trained social worker to help him in adjusting his private patients; or as is often the case, he may have to ignore all but the medical phases of his work. This is a regrettable thing, and it is in such and similar situations that organizations as the Committee for Health Service among Jews should extend and invite co-operation with physicians in the social care of the sick. Whichever method may be pursued, the modern physician realizes the need of some service supplementary to medical diagnosis and therapeutics.

The following table indicates the kind of medical social service which the physicians recommended as being needed by the 100 patients referred by them.

PATIENTS REFERRED FOR:

Boarding child	1
Convalescent care	27
Employment	12
Financial assistance	6
Further examination	16
Hospital care	28
Nursing care	1
Social adjustment	4
State Hospital admission	5
	<hr/> 100

A consideration of the reasons for which the 100 patients were referred presents a fairly complete cross-section of the several classes of service a medical social service agency is called upon to meet.

Boarding Children.—Arranging for the temporary boarding of children while the mother is ill, recuperating or attempting to become self-supporting is a form of service for which there is always a need. This particular instance is referred to above in a discussion of Case 3.

Convalescent Care.—There were twenty-seven patients who were referred for convalescent care following some severe illness or operation. To begin with, a word might be said regarding convalescent facilities for New York City patients. A survey made by the Public Health Committee of the New York Academy of Medicine, brought out the need of additional convalescent facilities and a better correlation of the available ac-

commodations. Certain types of conditions are fairly well provided for, while other types, such as nervous and borderline mental cases, are not adequately considered. A study of 3,236 case records selected at random from the files of the social service departments of a group of hospitals showed that in 908, or 30 per cent of the cases, there is a convalescent need. Convalescent care was obtained for practically every patient who was eligible for admission to a convalescent institution. Physicians occasionally referred patients for such care who were nervous or mental cases, or who had chronic physical ailments, thus rendering them ineligible for admission to nearly all convalescent homes serving New York City.

Employment.—There were eleven men and one woman referred for employment. In some cases it was possible to help them obtain such work as they could do; in other instances lack of cooperation and physical inability to work mitigated against any immediate solution of the employment problem. One patient was referred by a physician who advised him that he needed a certain out-door position in the classified civil service of the city. The patient was not a citizen, knew little English, and had absolutely no qualifications for the position in question. In other cases it was necessary to convince patients that due to their chronic state of ill-health their earning power had decreased and they would be compelled to take less remunerative work.

Financial Assistance.—In the few instances where application was made for financial assistance, a medical report was at once communicated to the relief organization for their investigation and further action. Those found to be in actual need of such help were aided.

Further Examination.—Occasionally a private practitioner has patients regarding whose diagnosis he is not sure, because he specializes in some branch of medicine, or because the patients may need to be x-rayed or to have various tests made for which they are unable to pay. Sixteen such patients were referred to the Committee and the recommendations of the physicians were carried out in every case.

Hospital Care.—The problem of the physician unaffiliated with a hospital is further emphasized by the fact that twenty-eight out of a hundred patients were referred for hospital care. Some were general hospital cases, while

about 50 per cent were chronic cases in need of a long period of hospitalization. While all patients could have been sent by their physicians to a city institution, and their admission practically assured, the request was as a rule for admission to some semi-private institution as the Montefiore or Mt. Sinai Hospital. Application was made for every eligible case, immediate arrangement being successfully made for all acute or semi-acute sufferers.

Nursing Care.—One patient was referred as being in need of nursing care and such was arranged for through the visiting nurses' organization.

Social Adjustment.—The four persons referred for some form of social adjustment other than employment were in each case either mental or nervous problems. One was a neurotic boy of seven years who was unmanageable at home as well as at school. The parents were in comfortable financial circumstances and arrangements were made to have the lad enrolled in a private school for problem children. Another patient was a boy of fourteen who showed certain anti-social instincts, was troublesome at home and dull at school. Application was filed for his admission to the George Junior Republic, the parents to pay for his care. A young woman of eighteen years, and a recent arrival in this country, was a psycho-neurotic who needed some one to be interested in her and to help her adjust herself to her new environment. She was placed in touch with an immigrant aid organization. The fourth patient was a girl of 16 years, who could not get along at home, and was otherwise maladjusted.

State Hospital Admission.—Relatives of mental cases in need of institutional care were advised regarding the care and treatment at state hospitals, as well as how to have patients admitted to the hospitals.

Some of the activities of the Committee for Health Service among Jews have been sufficiently portrayed in the preceding pages to indicate the need of some such agency in the larger cities of the country. Closer cooperation between physicians, hospitals, convalescent homes and the various social agencies in communities is essential, so that the sick may be more effectively served by the existing organizations. In smaller cities and towns, some existing agency should offer the various forms of co-operation to local physicians, if such is not already being done.

National Versus State Building Codes*

By SIDNEY J. WILLIAMS, CHIEF ENGINEER, NATIONAL SAFETY COUNCIL, CHICAGO, FORMERLY CHIEF OF BUILDING INSPECTION DEPARTMENT, INDUSTRIAL COMMISSION OF WISCONSIN.

A COMPREHENSIVE national building code, suitable for enforcement in New York and in Tulsa, in Sacramento and in Boston, is impracticable. In those parts of a building code which can be based on definite scientific fact, national uniformity is possible and is much to be desired. But there are other parts where scientific knowledge is lacking or uncertain; where regulations must be largely based on judgment; where the local legislator and jurist and the property owner himself think their judgment is as good as the engineer's; where the collective judgment differs in different sections and communities; where the actual needs of the community differ; and where enforcement of a uniform standard is out of the question.

Some of the objects sought by the advocates of a comprehensive national building code can be secured through the medium of state codes properly formulated and administered.

The need for uniform building codes, either state or national, has been long discussed by engineers and architects, with much caustic comment on the absurdity of conflicting city regulations. With all this agitation, there has been little substantial progress, largely because engineers and architects have not realized that the job is a diplomatic, quite as much as a technical one. The engineer is seldom a good diplomat, almost never a good politician. Yet often the politician comes closer than the engineer to the essential facts of life in a democratic commonwealth. Nowadays, engineers are gradually waking up to their opportunities as leaders of thought and action in non-technical fields, so there is hope that they may soon exercise such leadership toward better building regulation.

As soon as we analyze the building code job into its diplomatic and technical elements we find that the "versus" in our subject indicates not conflict but correlation.

Don't "Damn the Public"

Building regulation obviously consists of two things: first, formulating the code; and second, enforcing it. The latter is almost entirely an administrative or diplomatic job,

and the former is partly so. The problem that will be met with in administration must be anticipated when the code is formulated or the code is likely to be a failure. A wise mother once said "I don't want my children to disobey me, so I try not to ask them to do anything which I know they very much dislike to do." In a government which is not paternalistic, it is even more necessary for state or city officials not to try to make the public do something to which a large part of it will strongly object. Any such attempt generally results either in the administrative department quietly backing down and not enforcing the law, the legislature repealing the law, or the courts throwing it out or declining to convict under it because it is unreasonable. Any one of these things is very bad, much worse than successful administration of a law somewhat less "ideal" from the technical standpoint.

Uniform Structural Needs

A building code has for its purpose the protection of life, limb, and property. Its provisions may be grouped under four general heads: (1) Structural provisions intended to prevent collapse or excessive deterioration; (2) fire prevention and protection including exits and other safeguards for the occupants in case of fire; (3) sanitary requirements on such subjects as ventilation and lighting, intended to protect the health of the occupants; (4) prevention of personal injury during normal use of the building, such as hand rails, avoidance of slippery floors, protection against breakage of skylights. Most building codes do not contain enough on these subjects. Elevator regulations, if included in the building code, fall in this group.

City building codes generally also contain fragmentary provisions for preventing accidents to building workmen, as such as temporary floors on steel skeleton buildings. The treatment is almost always inadequate; the subject is really a separate one and should be covered in a separate code or law.

The formulation of structural requirements, allowable stresses for various materials, minimum thickness of walls and other dimensions, is definitely an engineering job which can be standardized. A steel bar is not 12

per cent stronger in Chicago than it is in Cleveland. Dwelling house walls in Philadelphia need not be twelve inches thick if eight inch walls are satisfactory in other cities. Mr. Ira H. Woolson and his committee have done a splendid piece of work in producing their report on "Recommended Minimum Requirements for Small Dwelling Construction," which reflects the best up-to-date technical knowledge and experience on structural requirements that are really necessary for safety and fire protection. This committee's technical achievement is equally by its wisdom in confining its first report to this comparatively non-controversial field. With the powerful backing of the U. S. Department of Commerce and, presumably, the support of the technical associations ably represented on the committee, this report should go a long way toward securing uniform reasonable city regulations on this part of the subject. It is much to be hoped that this committee or some similar committee will now go further and prepare standard structural provisions for larger buildings as well, which could be adopted by any city or state as the structural section of its building code.

The second subject included in building codes is fire protection including safety to life. Some parts of this field are now agreed on. The construction of chimneys and the protection of heating apparatus are covered in the recommendations of Mr. Woolson's committee and are not likely to arouse much antagonism. They might well be adopted by any city or state.

Safe Exits a Problem

Other elements of fire protection are more difficult and more controversial. The provision of proper exits to insure safety for the occupants in case of fire is a very complicated problem. It is easy to say, as some building codes do, that there shall be one stairway for every so many thousand feet of floor area. This simple solution is totally inaccurate as if one should say that all reinforced concrete must contain one per cent of steel.

The design of reinforced concrete structures is a science and art in itself and to design exit facilities that will be safe without being unreasonably expensive is almost as difficult.

*Presented at joint meeting Engineering Section of National Safety Council and American Society of Safety Engineers, New York, February 16, 1923.

We have to guess at some of the fundamental data. We cannot conduct laboratory experiments such as constructing a building with certain exits, putting a thousand people into the building, setting fire to it, and observing whether the people get out alive. True, we are burning down buildings every day, most of them contain people, some of the people do not get out alive, and then we make investigations and try to determine what was the matter and what improvements would have prevented the disaster; but these unplanned experiments are not under laboratory control and the conclusions drawn from them are often disputed.

We have, of course, some accumulation of data in this field, on which it should be possible to base a fairly accurate standard, but we must face the fact that the standard is a complicated one. For about ten years the National Fire Protection Association has had a committee on safety to life. This committee has done much valuable work, chiefly on exit requirements; recently it has been enlarged and has become a sectional committee under American Engineering Standards Committee rules to formulate a code on building exits. The standard which it is working out will represent the best available experience and judgment.

Ready Made Fire Zones

Other phases of fire protection are almost as fundamental and even more controversial. Perhaps one reason is that very few owners want their buildings to collapse because of structural weakness or to be fire traps because of insufficient exits, but many owners prefer to run some risk of property loss by fire, rather than go to the expense of fire resistive construction. Fire protection is largely a relative matter. It is not only excusable but it is economically right to take more chances of fire in building a general store in a frontier town than on Manhattan Island. As long as the owner can buy insurance on a combustible building, he will often choose to build such a building and will object most strenuously if he is not permitted to, unless he can be shown that it would constitute a serious conflagration hazard to adjoining property; and the legislatures and the courts are likely to take the same view, especially in the newer parts of the country. Therefore, it seems quite out of the question to have any national standard on the limits of combustible construction.

One suggestion has been made that

seems a sensible one. Almost every city has "fire limits" within which special requirements are imposed. Let us assume a series of two or three or half a dozen zones of fire hazard, the first representing the Wall Street district of New York, the last representing the cross-roads settlement in Kansas. Let the experts determine what sorts and sizes of buildings should be permitted in each zone. Then let each community zone itself and let fire insurance rates be fixed accordingly. In other words, extend into fire protection the same zoning idea that is becoming so generally used in regulating the height and congestion of buildings from the standpoint of health and general welfare.

In the field of ventilation and sanitation we are far from having a logical standard. Such standards as we have are empirical, without scientific basis. Ventilating engineers and physicians frankly admit that they do not yet possess the fundamental criteria for determining what good ventilation is. Investigations and researches are being made and we may hope, within a few years, to have as much scientific knowledge of good ventilation as the medieval architect had regarding the structural design of a Gothic cathedral. Meanwhile the best we can do is to strive for some sort of agreement or standard based on the best guesses of the best experts. Some of the codes included in the American Engineering Standards Committee program will be of help in this field.

The provisions of the average building code relating directly to accident prevention are, as I have said, very few and of comparatively minor importance. These subjects, too, are being dealt with in some of the American Engineering Standards Committee safety codes, and national standards thereon will be forthcoming in due course.

This survey of the situation proves the opening statement that a complete national building code is, to say the least, impracticable, although we should strive for, and may reasonably hope for, a considerable degree of uniformity on subjects where we have sound scientific knowledge and where consequently we can secure substantial agreement from technical experts.

If every city in the country were to adopt tomorrow the best possible building code, a large percentage of the buildings in the country would still remain without any regulation whatsoever. This is where the state building code comes in. The purpose

of a state building code is, first, to help in bringing about uniformity among the various cities in the state; and, second, to furnish protection to the people living in communities having no local regulation at all.

The relation between national standards and a state code is this: The national standards, formulated by the best experts of the land, should reflect the most accurate, most complete, and most up-to-date technical information available. The state code should take these standards and adapt them to local conditions and administrative exigencies. The state building code job, both formulation and administration, is almost entirely a diplomatic one, assuming, of course, that the officials in charge have enough technical knowledge to understand and apply the regulations that they are administering.

Function of State Codes

The relation between a state building code and the codes of municipalities within the state is most important and delicate. The authority of the state is superior to that of the city, but it does not follow that a state law can be enforced in a given city if it is obnoxious to both the inhabitants and the city officials. The state is the mother and the cities are her children, but, like the wise mother I have already mentioned, the state should not ask her children to do things that they too violently object to. Better say nothing about superior authority, but "sell" the city officials as far as possible on the newer and better standard, cheerfully accept a compromise, and then conduct a patient campaign of education among city officials and people alike looking toward a better standard later.

This implies a great amount of elasticity in the administration of the state code. That is one reason why there have been few, if any, examples of success with building regulations passed by a state legislature. A statute law is not elastic but rigid. When once passed it can only be amended when the legislature meets again, and sometimes not even then. Therefore property owners and even engineers and architects are, not without reason, afraid of a state building code passed by legislative enactment. If such a code is proposed, they scrutinize it most critically; they look for any little point that might, if rigidly enforced, cause them trouble or unreasonable expense; if their suggestions are not adopted, they oppose the entire code. With one interest objecting to this provision,

and another to that, the total opposition is more than enough to kill the code. Several states have spent thousands upon thousands of dollars and many architects and engineers have given days upon days of their time without recompense in the formulation of a building code to be presented to the legislature, and year after year the codes have failed of enactment, for this reason.

Then how can a state building code be secured? In exactly the same way that most of the progressive industrial states have secured regulations covering elevators, or electrical equipment, or the safeguarding of machinery, through the medium of orders formulated and enforced by an administrative commission. One example is found in Wisconsin where a code covering all buildings except one and two family houses was adopted ten years ago by the Industrial Commission and has been enforced by it ever since, with a fair degree of success. A brief account of the procedure followed may be of interest.

First the law was amended so as to extend the commission's authority to cover buildings used or frequented by the public or by three or more tenants, as well as places of employment. When this amendment was passed, probably few members of the legislature and still fewer of the general population realized that it meant a state building code. The commission took care that this realization should not come too violently. Had the commission adopted and tried to enforce a building code like that of New York or Chicago, the result would have been a storm of protest and the next legislature would undoubtedly have repealed the amendment. What the commission did was to formulate a code as simple and brief as possible, that would correct the most glaring life and health hazards then existing. Great care was taken to consult all architects and engineers as well as city officials and to accept their majority opinion as to what could reasonably be enforced. In the one city then having a real building code of its own the local officials were assured that the commission did not intend to override or duplicate their local inspection.

At first the commission did not require, but only suggested, the submission of plans for approval. This is an example of the careful approach by which the support of engineers, architects, and builders was gradually secured. Later a requirement for the submission of plans was

added, without opposition. At the same time, the cities were encouraged to adopt building ordinances of their own and appoint local inspectors. The state commission delegated its work to these local men, keeping in touch with them and assisting them.

Undoubtedly this ten years of state building regulation has raised the standard of building in the state considerably and many thousands of buildings constructed within that time are much better and safer places to live and work in than they would have been without the code. Meanwhile, other states which ten years ago were talking about a building code, are still talking about it.

To summarize:

(1) In any discussion of building codes it must be remembered that the diplomatic job of enforcing the code is quite as important and generally more difficult than the technical job of determining an ideal standard. (2) The technical job of determining ideal standards can best be handled on a national basis, by representative committees of experts. (3) A complete national standard building code probably cannot be formulated at this time, but many sub-divisions of the subject can and should also be so standardized; several such projects

are already under way. (4) Every effort should be made to have local ordinances amended to conform to these national standards and to have such standards adopted by municipalities which now have no building codes.

(5) State building codes are very desirable, to help bring about uniformity and to cover communities having no local regulation. (6) The administration of state codes must be carefully handled, and the desire of all cities for self government should be respected. (7) From the practical administrative standpoint it is better if the state code is considerably shorter and simpler than the usual city code. A short simple code is generally sufficient to take care of the smaller towns and the larger ones can adopt more complete regulations of their own. (8) It is difficult and probably undesirable to have a detailed state building code adopted by the legislature. It is quite as effective, and much more practicable to give an administrative commission authority to adopt and administer a code. The law should of course provide proper safeguards, such as the use of a technical advisory committee and the right of appeal to the courts in case the commission should exercise its authority unreasonably.

Good Roads and Health

THE interdependence between general community improvement and community hygiene has been frequently noted but it is all the more apparent in those situations in which conditions are backward or primitive.

The Isthmus of Panama represents one of the oldest civilizations in the new world and, in the area occupied by the Panama Canal and its immediate environs, it has served as a great international highway for centuries. That portion of the Isthmus has therefore been kept in touch with the outside world and has been correspondingly affected by the progress of other peoples. Communication with all portions of the Republic remained very difficult however, until the trans-isthmian railway was completed in 1855. From that date the terminal cities of Aspinwall (now Colon) and Panama began to advance. With this exception, travel in other parts of the Republic has remained exceedingly difficult until very recently when the Junta de Caminos (Central Road Committee) launched its road building program under the aegis of Dr. Beli-

sario Poras, the president of Panama. This work has proceeded rapidly and roads of good engineering design and construction have been built.

The first stretch completed, connected the City of Panama with Tapio, which formerly was a little palm-thatched village sprawling in filth along a road which was a bog eight months in the year and a series of sunbaked corrugations in the dry season. The policy of maintaining the edges of the new road free of vegetation was adopted and within a short time, the yards of the adjacent houses began to take on a neater appearance which has progressively improved. Here was the first step in community improvement and pride of appearance taking place through imitation. The new road made it possible for the villagers to transport their produce easily to the capital and, in consequence, an improvement in economic conditions has followed, as evidenced by an increasing prevalence of shoes which in turn without doubt will serve to reduce hookworm disease.

In Los Santos province, a road has been practically completed, connecting

Mensabé, Las Tablas and Chitré. All of these places were very backward and insanitary only a few months ago. Communication was accomplished by saddle horses or ox carts and during the season of heavy rains the movement of persons and freight was practically impossible. As a result these towns, which were old when New York was first settled, stagnated by reason of their virtual isolation from the outside world, the more energetic youths of the community leaving them for residence elsewhere. Las Tablas, which a year ago was anything but sanitary, has recently built a sanitary abattoir and market and is rapidly being transformed into a clean little town and the community conscience has been quickened to other improvements. Chitré now has a good little hospital and is approaching its public health problems with spirit.

Another road is being built to connect Aguadulce, Santiago, and Natá; in fact, it is almost completed. Aguadulce has recently created a small but adequate hospital and in cooperation with Pocrí, a neighboring village, has recently erected a sanitary abattoir. Thus the local Chauvanistic spirit is giving way to the modern spirit of cooperation. The new road to the Port of Aguadulce has resulted in improved steamship service and large quantities of fruit and farm produce for which there was formerly a scant market are now being shipped to Panama. Until this year, turkeys in Aguadulce never cost more than three pesos (\$1.50) but this year they sell for six pesos (\$3.00) and there is a ready market for them, since buyers can get them readily to the Port and into Panama. Aguadulce is now arranging a loan from the central government in order to make a number of municipal improvements, including a modern water supply.

Santiago and Natá will soon be reached by the road and a similar set of improvements may be anticipated in them. It will be particularly interesting to note the changes in Natá. This is said to be the oldest town on the Isthmus of Panama and occupies the site of an Indian village of great antiquity on a fertile plain of great beauty. Originally known as Natá de los Caballeros (Nata of the Gentlemen), it has been shut off from the outside world by the Rio Chico which is uncertainly passable for at least eight months in every year. Stagnation and degeneration were inevitable under such conditions. Many of the fields are idle, the public water supply is still brought from the river (about a kilometer) on the heads of

women and conditions in the so-called hospital are truly mediaeval. Even the fine old church, in which it is alleged there is a Velasquez, is beginning to fall into decay. But with the completion of the road and the bridge across the Rio Chico, an easy communication with the Port of Aguadulce will be created and this five-century old village will undergo in all probability an enormous economic and therefore sanitary advance. A benign circle of increased health and increased wealth will thus obtain.

It may be impertinent to add that many sanitarians are apt to ascribe to the science of Hygeia victories in which it only played a part. Sanitary advance is only a part of general community advancement. Sanitation may try to head the procession, but the community cannot follow unless there is a simultaneous economic improvement. Public health cannot stalk ahead as a solitary figure. It must walk side-by-side with increased earnings, with increased education, with better markets, and, above all, with better means of commercial intercourse. Sometimes we are downcast because the community does not respond more quickly to our efforts for sanitary and hygienic advancement. If we will remember that these keep pace with the dinner-pail and the bank account, we may be more patient and less critical. A people which is backward economically will be backward hygienically and to improve either, one must improve both. The good road is at once the most certain and the most rapid means of accomplishing this.

Progress of the Framingham Demonstration

The Framingham tuberculosis rate, as indicated by the table below, is considerably higher than the very low rate of 1921.

Rate per 100,000

Pre-Demonstration Decade	
1907-1906	121.0
1917	97.5
1918	84.7
1919	90.2
1920	64.5
1921	40.1
1922	67.2

Variations from year to year must be expected in so small a population group. The average rate for 1921 and 1922 is, however, only 53.6, a reduction of 55 per cent below the pre-demonstration average. The group of control towns, used as a norm in previous years, show an average rate of 98.0 for the two years 1921 and 1922, a reduction of only 22 per cent below their 1907-1916 rate of 125.9.

The number of cases of tuberculosis reported in Framingham rose from an average of 13 cases a year for the pre-demonstration period to 45 in 1919 and has since fallen steadily to 24 in 1922. It is also particularly encouraging to note that of these 24 cases 16 were in an early stage.

The British-American Nursing Home, whose establishment was made possible largely through the efforts of Keith Merrill, the American Consul, and Mrs. Merrill was recently opened in Madrid. The Nursing Home, the first of its kind in Spain has modern equipment and a staff of specially trained nurses.

After-History of Tuberculosis Patients

Year		Notified as of Previous Years of Primary Tuberculosis														Notified as "Other Forms" of Tuberculosis
		1912	1913	1914	1915	1916	1917	1918	1919	1920	1921	1922	Attended Dispensary	Not attended Dispensary	Visited by Dispensary nurse

Total	6473	354	323	375	409	416	431	391	342	371	383	1927	728	135	6504	74

*Included in the gross total of 1-10 for the year 1912 40 cases notified prior to that year.

The annual report of the Medical Officer of Health of Newcastle-upon-Tyne for the 1921 contains the very interesting table below from which one may gain a fairly complete view of the after history of reported cases of tuberculosis. It appears that practically every year more than a third of the cases died in the year they were originally reported. About one eighth more died in the second year and for those who did not die in the second year the prognosis was apparently good. Other statistical tables in the report indicate that the average duration of illness for fatal cases was 31.6 months so that the patients dying in the year of report must on the average have been ill for nearly eighteen months before notification.

Pasteurization Minimizes Milk Borne Epidemics*

But Health Officer Must Enforce Rigid Sanitary Rules to Keep Supply Clean

By THOMAS G. HULL, PH.D., CHIEF, DIVISION OF LABORATORIES, ILLINOIS DEPARTMENT OF PUBLIC HEALTH, SPRINGFIELD, ILL.

THE Illinois Department of Public Health is vitally interested in milk because of its food value and the necessity of an adequate supply to all communities of the state. The department is emphasizing the necessity of a safe milk supply, however, because of disastrous accidents which have repeatedly taken place in the past.

Several factors are to be considered in judging milk. It should have sufficient cream, at least to come within the law. Undue emphasis can be placed on this factor from a public health standpoint, however, because no epidemics, no disease, no deaths have ever been traced to a deficiency of butter fat. This is entirely an economic problem.

Next, milk should be sweet when delivered to the consumer. Milk is rendered sour by the growth of bacteria which produce lactic acid. The bacterial count, which is in the final analysis only an indication of the keeping qualities of the milk, does not necessarily indicate either pollution with dirt or contamination with disease bacteria. For infant feeding, however, it is absolutely essential that milk be as sweet and fresh as possible, for the digestive tract of the infant is overwhelmed by mere numbers of bacteria alone. The so-called "summer diarrheas" of babies are often the result of a milk that has not been kept sufficiently cold to prevent rapid bacterial growth.

Dirty milk is never excusable. There is a peculiar psychology about the presence of dirt in milk. A farmer may fly into a rage or become nauseated on finding a hair from the clean head of his wife in his food. He will go directly to the stable, however, to do his milking, straining out of the milk with a piece of cheese cloth, junks of cow manure, cow hair, flies, bugs, straw, dandruff, and other dirt. Then he drinks copiously of this product, bragging about his wonderful milk supply. Dirt in milk may be of significance from two standpoints, the esthetic, whereby we demand that milk be as free from such material as our other foods; the other, that of

public health where we insist that cow manure containing dangerous tubercle bacilli, or human feces carrying the deadly typhoid germ, be absolutely barred from getting into the milk.

This leads us directly to our last point—milk must be safe. It must produce no diseases, no epidemics, no deaths among those who drink it. The Illinois state department of public health is vitally concerned in this matter for too often local communities give no heed to advice and warnings regarding their milk supplies till after the epidemic has struck, when in desperation they call the state's help.

There are in our files, record of more than four hundred epidemics with thousands of cases of typhoid fever traced directly to contaminated milk. There are innumerable other instances of which we have no record for they have been so common that only part of them have been reported in the scientific literature. It is only necessary to cite a few outbreaks that have occurred in Illinois. In one of the state institutions in Morgan county typhoid fever was becoming more and more prevalent till about a year ago investigation showed the milkman to be a typhoid carrier. With his removal, cases of typhoid fever ceased to occur. In Carroll county, one of the small towns was continu-

ally reporting typhoid fever. Suspicion pointed to a "three cow" dairyman who had had typhoid fever forty-three years before. Laboratory examination of his stools showed 95 per cent of the organisms developing to be typhoid bacilli. In Bond county, twenty cases of typhoid fever with several deaths occurred in one community over a period of six months. Investigation showed that typhoid fever existed on two farms from which the milk came and that accidental contamination had occurred from time to time. In Henry county, twenty-five cases of typhoid and two deaths occurred within a few weeks. The dairyman whose milk was responsible for the epidemic purchased milk from seven farms, distributing it to his customers without pasteurization. On one of the farms was a typhoid carrier, detected by laboratory tests, who had infected the milk. Incidentally, the dairyman X not only lost every dollar he had because his business was ruined, but he almost lost his life, contracting typhoid fever along with his customers.

An incident showing the efficacy of pasteurization in blocking contagion may be cited. In the northern part of the state on one of the farms there occurred several cases of what was termed "summer flu,"—one after an-

Milk distributor X bought his milk from seven farms distributing it without pasteurization. On one of the farms was a typhoid carrier who infected milk with the result that twenty-five cases of typhoid fever and two deaths occurred. Pasteurization would have prevented this epidemic.

*Read at Streator, Ill., November 9, 1922.

other of the family contracting the strange malady. The true nature of the disease was not ascertained till one of the sons died when a diagnosis of typhoid fever was made. During all this time milk from the farm was being shipped as usual. A small amount of milk went to a nearby village where it was consumed raw by a family of three persons. All of them contracted typhoid fever. The remainder of the milk was shipped to Chicago where it was pasteurized. No evidence of milk-borne typhoid fever appeared, because all the typhoid germs had been killed in the process of pasteurization. In Chicago, from 1911 to 1916, with only part of the milk pasteurized, thirteen epidemics of typhoid fever occurred that were traced directly to infected milk; from 1916 to 1922, with compulsory and efficient pasteurization, there is no record of a milk-borne typhoid epidemic.

Records are filed in the department of hundreds of epidemics of other diseases,—diphtheria, scarlet fever, and streptococcus sore throat traced directly to infected milk with the same story of infection often unsuspected by the farmer or dairyman himself till it was too late and the milk had been sold and consumed without proper pasteurization. In Chicago, in 1912, there occurred an epidemic of streptococcus sore throat estimated at 10,000 cases. At that time pasteurization of milk was not compulsory, nor was there any check on the plants pretending to pasteurize. At Michael Reese hospital where milk from the infected supply was used, a large number of cases occurred including nurses and interns. Milk for the children's ward of the institution was

pasteurized at the hospital as a matter of routine. The result was that not a single case of streptococcus sore throat appeared among the seventy children there.

Poor Milk Child Menace

The danger to infants and children of using a poor milk supply is well known. There are two factors involved:—the presence of disease bacteria and enormous numbers of other bacteria, not necessarily disease-producing in themselves, but which overwhelm the digestive tract of the infant, bringing on digestive disturbances. In the summer time, when the weather is hot and ice difficult to obtain, bringing in sufficient quantities, infant diarrhea due to bad milk is especially prevalent. In New York City Nathan Straus began the distribution of pasteurized milk in 1892. The summer death rate (June, July and August) of infants then stood at 136.4 per thousand. Fifteen years later, with the extension of milk stations and the increase in the use of pasteurized milk, the summer death rate had been decreased to 62.7 per thousand. Another striking incident occurred at Randall's Island in New York Harbor. At a children's institution there before the days of general pasteurization the death rate was very high, being 41.8 per cent for the years 1895, 1896, and 1897. The milk used in the institution came from a herd pastured on the island. In 1898 a pasteurizing plant was installed, no other hygienic measures being instituted. Immediately the death rate was cut in half and for the next seven years lay at 21.7 per cent. Usually the opponents of pasteurization object to the process

for the sake of the children. As a matter of fact, it is the children who require pasteurized milk and who suffer most when fed ordinary raw market milk.

In milk borne tuberculosis the condition is dependent not so much on healthy individuals handling the milk as on healthy dairy cattle. Milk may become infected with tubercle bacilli in two ways. When a cow has tuberculosis of the udder, the milk will contain millions of virulent tubercle bacilli. In tuberculosis of the lungs, the cow coughs up material but instead of expectorating it, swallows it and passes it out in the manure. The careless milkman gets some of this cow manure into the milk, thus contaminating it with tubercle bacilli. Ordinarily, market milk is infected with the germs of tuberculosis in about 10 per cent of the samples. In New York City some years ago, 16 per cent of the milk was so infected; in Washington, 6.7 per cent; and in Chicago, 10.5 per cent. Recently a study was made in New Haven, Conn., where 50 per cent of the milk was found to harbor sufficient tubercle bacilli to infect guinea pigs with tuberculosis. Fortunately, all this milk was pasteurized, after which it was impossible to infect guinea pigs, all the disease germs having been destroyed. Recently, a specimen of milk from one of the herds supplying milk to Streator, Ill., was brought to the laboratory of the state department of public health. A single drop showed innumerable tubercle bacilli, as many as twenty organisms in one microscopic field.

Children suffer most from bovine tuberculosis. In a study in New York City, among adults afflicted with tuberculosis, only about one per cent showed the bovine type of disease while among children suffering from tuberculosis, more than 25 per cent of the cases were due to the bovine tubercle bacillus.

Considerable misconception seems to prevail in some localities over the object of pasteurization in that it is to be made a substitute for tuberculosis eradication in cattle. This is not true. Pasteurization can never be made a substitute for tuberculin testing, neither can tuberculin testing be made a substitute for pasteurization. The two must go together. The state department of public health is solidly back of the state and federal departments of agriculture in their campaign for tuberculosis eradication among dairy cattle.

Opponents of pasteurization further

Several cases of typhoid fever occurred on a dairy farm. Some of the milk was shipped to a nearby community where it was consumed raw by a family of three persons all of whom contracted typhoid fever. The remainder of the milk was shipped to Chicago where it was pasteurized. No typhoid resulted.

claim that the process destroys the food value of milk. This is true to the extent that the so-called "vitamin C,"—the substance which prevents scurvy,—is destroyed by the heat required in pasteurization. Not all milk contains this substance, however, which depends upon the feed of the cow. Investigators in the United States Public Health Service have shown that even expensive certified milk cannot always be relied upon to contain vitamin C but that orange juice or other fruit juice should be added to the infant's diet in all instances. The other food properties of the milk,—the growth promoting substances, fat, salts, sugar, protein,—are in no way impaired by pasteurization.

Clean Milk Imperative Also

Another criticism of pasteurization is that it is a substitute for cleanliness and that dairymen use it to cover up their dirty habits. This is a matter for each local community to solve and is in the hands of your local health officer. Milk unfit for human consumption must never be put on the market in the form of a pasteurized product. An efficient inspection service can easily take care of the problem.

It is also claimed that pasteurization increases the cost of milk. In answer to this, the case of Quincy, Illinois, may be cited. Here a number of raw milk dealers organized for self preservation, a company was formed, stock sold, a pasteurization plant built. This milk is now being retailed to the consumer for the same price as formerly while the farmer is getting the highest price in the state for his milk.

"Certified" milk is a copyrighted name and can be used only by permission of a medical milk commission which "certifies" to the public the suitability of certain milk for infant feeding. Such elaborate precautions are required in the production of such milk, however,—frequent veterinary examination of cattle and medical examination of milkers and helpers,—that the cost is usually 25 to 30 cents a quart. Even then the certified milk is not always safe, contamination with disease organisms sometimes occurring. Recently, in Chicago, a little girl died of streptococcus sore throat infection contracted from certified milk.

It is unnecessary to go into the details of the process of pasteurization. There are various methods and modifications but any machine that will hold the milk for thirty minutes at 142° F. to 145° F. is satisfactory. It has been found by experiment that the disease bacteria such as the

typhoid bacillus and streptococcus are killed in a much shorter time,—ten to twenty minutes at 140° F. The extra time and extra temperature are given as factors of safety. From 95 to 98 per cent of the lactic acid bacteria are killed but some remain so that the milk will eventually sour normally, though much more slowly.

A proposed milk ordinance has been

drawn up with the cooperation of the state department of public health, the state department of agriculture, the University of Illinois, some twenty municipal health departments in the state and a larger number of representative milk producers and milk dealers which if passed by municipalities will insure the absence of milk borne epidemics.

A Tuberculosis Program

BY DONALD B. ARMSTRONG, M.D., SECRETARY, MILBANK FUND. TECHNICAL BOARD, NEW YORK CITY.

IN CONNECTION with the Health and Tuberculosis Demonstration plans of the Milbank Memorial Fund it has seemed worth while to attempt to outline a fairly comprehensive, though somewhat hypothetical tuberculosis program. Such a program aims to be of value in suggesting activities in the proposed demonstration units, and may also serve as an underlying basis against which to contrast the relatively inadequate and varying programs as they stand today in other communities. Obviously, such a program very nearly approximates a thorough-going general health plan.

It is generally assumed by tuberculosis and health workers that there may have been in the last few decades a more or less natural or normal decrease in the tuberculosis mortality rate, as a result of social and possibly biological factors of an uncontrollable character. It also seems to be a reasonable assumption, or perhaps conclusion from available data, that this natural decrease has been accelerated by certain special and accessory measures. From this point of view Dr. Haven Emerson has recently developed a classification of the influences at work somewhat along the following lines:

(1) Specific measures, such as medical examinations, milk pasteurization, and hospitalizations.

(2) General accessory measures, such as infant welfare work, and personal hygiene education.

(3) Accidental measures, such as changes in race stocks or alterations in economic conditions.

From the point of view of the rational use of these influences, as they may be worked into a practical program, there has been attempted a redistribution of the factors, still on a theoretical and hypothetical basis, but in line with the logical utilization of the measures involved in practical work.

Space does not permit of anything more than the briefest itemization.

(I) Measures against tuberculosis infection: (1) Milk pasteurization and tuberculin testing of cattle. (2) Meat inspection. (3) Fly control. (4) The elimination of common utensils and the proper cleansing of eating utensils. (5) General respiratory hygiene, including sputum control. (6) Control of open cases, protection of infants from tuberculous mothers, hospitalization, etc. (7) Personal hygiene of the defensive type—educational measures to eliminate the spread of infection. (8) Housing, less congestion, decreased contact, etc.

(II) Measures against disease:

A.—To increase resistance: (1) Infant hygiene—breast feeding, nutrition, etc. (2) Pre-school work—nutrition, elimination of other diseases, and defect removal. (3) School hygiene—defect removal, disease control, nutrition, open air rooms, camps, preventoria, school sanitation, and personal hygiene. (4) Industrial hygiene—improved working conditions, personal hygiene, education, etc. (5) Improved home living conditions—the equipment for cleanliness and hygiene, such as light, air, bathing facilities, etc. (6) General personal hygiene—especially of the creative type—exercise, air, food and dental hygiene. (7) Improved economic conditions—stable employment, better wages, fewer hours, ability to buy better food, housing, clothing, and such matter. (8) Prohibition and elimination of alcohol consumption.

B.—To detect disease (especially in early stages): (1) Clinics and dispensaries. (2) Nursing Service. (3) Routine medical examination machinery provided through infant and pre-school clinics, school examinations, and factory examinations. (4) The specialist consultation service. (5) The education of physicians in diagnosis, reporting, etc. (6) Lab-

oratory facilities. (7) Health examinations.

C.—To treat the ill: (1) Clinics. (2) Home nursing, with relief and means to promote hygienic education. (3) Sanatoriums. (4) Hospitals, camps, home hospitals, etc. (5) Occupational therapy. (6) Social and economic follow up of arrested cases.

(III) Measures against mortality (either to prevent or postpone).

A.—Specific measures: This group includes practically all of the anti-tuberculosis measures listed under (II).

B.—General factors, more or less uncontrollable, that presumably affect

the mortality rates. (1) Race group changes in the makeup of a community population. For instance, Irish, Negro, German and French Canadian stocks in this country have relatively high rates, whereas Jews and Italians have relatively low rates. (2) Influenza epidemics—possibly through the fatal selection in certain age groups of individuals who would otherwise have contributed to subsequent tuberculosis mortality rates. (3) The war—deprivation resulting in higher rates and hygienic control and instruction for the industrial age group resulting in lower rates. (4) Climate.

elaborate program for theoretical and practical courses in hygiene which were put in force in twelve different arrondissements in Paris during the past year. The German Red Cross has recently organized an exceedingly interesting program of study voyages for young people. "These voyages were offered by the German Red Cross as prizes in a literary competition on the subject 'Description of the institutions for social welfare in your city.' From among hundreds of competitors thirty were chosen for the awards—eight girls and twenty-two young men. The thirty thus chosen were sent on a journey to a number of the leading cities of Germany and visited the various institutions of public health and social welfare which might be considered as models of their kind.

"These voyages lasted approximately two weeks and awakened in the young people an active spirit of emulation and a desire to participate in the work being done in their own cities, to combat disease and to secure an amelioration of health conditions. Their letters and the reports prepared by them on their experiences have given proof of the excellent results obtained."

Program of Red Cross League

A RECENT memorandum prepared by Sir Claude Hill, director general of the League of Red Cross Societies, outlines the public health program of the League as follows:

(1) The League is the International Secretariat of the (42) Federated Red Cross societies.

(2) The fundamental purpose underlying the international activities of the Red Cross in time of peace is to cause national Red Cross societies to endeavor to remove popular ignorance as to personal and public hygiene and thus: (a) to enable the public to take intelligent advantage of the public health measures devised, by whatever agency, for their benefit, and (b) by avoidance of preventable illness and disability to achieve a higher standard of living both in the material, industrial and in the moral sphere.

(3) With this end in view, the general council of the League, at its session in March, 1922, approved of a definite program of activities which desired that the League Secretariat should stimulate and national societies, members of the League, should adopt.

(4) The basic principle of that program is the propagation of knowledge of hygiene. The methods advocated were: (a) direct intensive popular health instruction through substantive activities, in defined areas, adapted to local needs and conditions; (b) prevention of sickness through the activities of public health nurses, and (c) stimulation of the Junior Red Cross movement.

This last, is a "within-school" movement, which, if it is to achieve success, must secure the support and guidance of the teaching profession upon which it absolutely depends. It aims (i) at inculcating health principles through an acceptable form of "games," teaching pride in personal cleanliness and health, (ii) good citizenship and unselfishness, and (iii) international interest and understanding.

(5) In order to achieve widespread and satisfactory results it is

necessary to popularize membership and, so far as conditions permit, to democratize the organization of Red Cross societies.

This is necessary, not only because it is a condition precedent to getting the general public to interest themselves in, and benefit by, hygienic knowledge, but also because, if national Red Cross societies are to achieve real and permanent results, they must be able to influence as well as to be useful coadjutors with, the state's health organization.

(6) The policy of the League Secretariat, as a corollary of the program approved by the national societies, is (a) to stimulate and assist activities by individual National Societies on the lines laid down; (b) to inculcate the principle that, whenever circumstances permit, activities so stimulated should cease to be a Red Cross responsibility and be taken over by the state or other appropriate organization; (c) to advise national societies to aim at securing:

(i) that the health administration of their countries shall regard them (the Red Cross societies) as indispensable adjuncts in the field of public health, and

(ii) that their methods shall be such that other non-official health agencies shall recognize the Red Cross, not as a competing but as a co-ordinating and complementary agency in the same field.

The League extended its influence to the Far East last fall through a very successful Red Cross conference at Bangkok, November 28 to December 7, and recently bulletins from the headquarters of the League in Paris indicate encouraging progress in the field of Red Cross health educational activities in many countries. The Belgian Red Cross has issued an admirable printed outline of courses in hygiene for the use of its chapters, the Scottish branch of the British Red Cross is organizing a series of health lectures in the county of Aberdeen, and the French Red Cross has an

British Death Rates Lowest on Record

The annual report on British vital statistics shows that great advances have been made in preserving adult and infant life. The death rates of the United Kingdom, 12.1 for males and 11.3 for females, are the lowest on record. In the decade 1841-1850 the death rate was 22.4, so that if that had prevailed the deaths in 1921 would have been 850,000, instead of 450,629. The rates are lower than ever before in all the aggregates up to 65.

The rate per million of population for deaths from tuberculosis is 1,127, the lowest in eleven years, as were the rates from bronchitis and pneumonia. The cancer rate showed a slight increase and was higher than in any year since 1918, the greater part of the increase being among females.

Infant mortality was 83 per 1,000 births, the lowest recorded except in 1920, when it fell to 80. Last year's rate is 25 per 1,000 lower than the average rate of the five pre-war years. Had deaths under one year been at the rate obtaining seventy-five years ago, they would have numbered 129,500, instead of 70,240, showing a saving of some 60,000 infant lives.

Health Program for the American Red Cross*

THE American Red Cross has, for a period long antedating the Great War, included public health work among its major activities. Through its nursing services, through classes in home hygiene and nutrition and through leadership in the field of cooperative organization of voluntary health agencies, it has made contributions of fundamental importance to the cause of public health. Through its primary part in the establishment of the League of Red Cross Societies, the American Red Cross has even assumed a certain sponsorship for the concerted spread throughout the world of the conception of the Red Cross as a constructive peace-time health agency.

Yet, in spite of the special activities noted above, the American Red Cross has, itself, today no real health program—in the sense of a concrete and comprehensive plan of activity which it can recommend as a basic foundation for local action throughout the country. We are well aware that the chapter is the ultimate source of action; but it is as clearly the function of the National Organization to formulate general programs and to exercise leadership in securing their acceptance by the chapters. That no health program has yet received any such general acceptance is indicated by the fact that on September 30, 1922, out of 2,960 chapters reporting, only 33 per cent were maintaining classes in home hygiene and care of the sick, 10 per cent were conducting public health nursing, 14 per cent were making specific efforts to coordinate the work of local health agencies, and only 8 per cent were holding nutrition classes.

The problem laid before your Advisory Committee is, as we understand it, whether the individual health activities of the American Red Cross as carried on at present should be curtailed; whether they should be maintained on their existing basis; or whether they should be developed and coordinated into a health program of sufficient appeal to attract a wider chapter response than has hitherto been manifest.

The advisory committee is unanimously of the opinion that the last

mentioned alternative is the one to be adopted. The charter of the American Red Cross clearly lays upon it the responsibility of preventing as well as of alleviating, the suffering created by preventable disease. Abandonment of health activities is therefore out of the question, and if health work is to be performed at all it seems to us clear that it will gain immensely in efficiency by fuller coordination and more definite emphasis.

From the standpoint of the public health worker and that of the practicing physician, the committee believes that there is a unique need and a unique opportunity for such a health service as the American Red Cross could render. The protection of the public health is fundamentally a governmental problem; but it is a problem which requires for its solution not only official action, but also the intelligent and active cooperation of the individual citizen. Modern wars are not waged by armies alone. The munition worker, the transport worker, the miner, the farmer, play a part as essential as that of the soldier. The war against disease must also be a war of the whole people. Such primary requirements as water supply and waste disposal systems may be provided and quarantine regulations enforced by the governments; but the most important problems of modern public health can be solved only with the voluntary cooperation of the individual citizen.

The object of the public health worker of the present day is to change the daily habits of life of the woman in the home and of the man at the desk and workbench. Such a change cannot be effected by laws, but only by the slow process of education. In recognition of this fact the public health movement in the past ten years has become more and more definitely educational in its very essence.

The Health Study Class

It is in connection with this great educational campaign for public health that the Red Cross finds its supreme opportunity for leadership. Non-political and non-partisan, established in the confidence of the people as the greatest practical world force for the concrete expression of the ideal of service to humanity, with vast potential membership and an organization which can be developed so as to reach into every hamlet, the Red Cross, and the Red Cross alone, can

successfully effect the mobilization of popular sentiment which is necessary to make the control of preventable disease a solid reality.

It has been well stated that "the function of the chapters of the American Red Cross in the health field is the promotion of individual and community health through personal service, group instruction and general health propaganda." Personal service, as a rule, however, should be conducted by the Red Cross during a definite demonstration period, to be turned over as soon as possible for routine administration to the constituted health authorities. In other words, even such actual services as public health nursing are rendered by the Red Cross as educational demonstrations. Education is the center and the essence of the Red Cross health program.

We would recommend, in order that the full possibilities of Red Cross health education service may be realized, that the home hygiene and nutrition work now conducted by the Red Cross be incorporated in a more extensive plan which would aim at the organization within each Red Cross chapter of a health study group—for the consideration (1) of the principles of personal hygiene and (2) of local community health conditions and health needs. This study class or health committee would thus become a continuing force for the support of the public health program in the community served by each chapter—an organized expression of that voluntary interest and voluntary support which are so essential to the conduct of the modern public health campaign. Particular applications will differ in different communities; but there is no single chapter of the American Red Cross which has not members who would benefit by a study of personal hygiene; there is no single chapter which by an intelligent survey of its local health situation could not find some opportunity for concrete service. The development of health study classes and neighborhood health service committees should, we believe, form the basic and universal element in a comprehensive health program; and the national organization should, in our judgment, take a definite and vigorous lead in this matter by preparing outlines of organization, syllabi for lectures and conferences, plans for surveys and suggestive standards for health programs.

*Report of the Advisory Committee authorized to outline a health program for the American Red Cross. Personnel of committee: William H. Welch, chairman; Herman M. Biggs, Thomas S. Cullen, Hugh S. Cumming, Livingston Farrand, Franklin H. Martin, Fred E. Lund, George Morris Piersol, John H. J. Upham and C.-E. A. Winslow. Reprinted from The Red Cross Courier, March 10, 1923.

Although the fundamental objectives of the Red Cross health program should be educational, it is obvious, as we have pointed out, that the best form of community education will often consist in the demonstration by a chapter of the value of specific community health services, wherever possible with the cooperation of other health agencies. Public health nursing and the coordination of existing community health agencies are excellent examples of such demonstrative community health education; and the health study classes will prove an invaluable medium for revealing opportunities for constructive services of this type.

As important integral parts of a health program based on health study and health demonstration we desire to express our hearty approval of the following policies of the Red Cross as at present formulated:

(1) The organization of classes in home hygiene and the care of the sick.

(2) The organization of classes in nutrition.

(3) The organization of classes in first aid and life saving.

(4) The health phases of the Junior Red Cross program, such as (a) the development of personal health habits; (b) participation in a school health program; and (c) participation in community health programs.

(5) The enrollment of properly qualified nurses under the Division of Nursing Service.

(6) The organized development of public health nursing in rural and semi-rural districts, through the activity of the Division of Public Health Nursing.

(7) Assistance in the development and standardization of the training of public health nurses through loans, scholarships, subsidies and the like. (This work of the Red Cross could with advantage be materially expanded in cooperation with the National Organization for Public Health Nursing.)

(8) The development of machinery for the coordination at one central point of the work of various local health agencies.

(9) Cooperation on a national scale with such organizations as the National Health Council for the purpose of furthering the coordination of voluntary public health activities.

Dangers to Be Avoided

If the Red Cross health program is to avoid reasonable criticism it must be so framed and so executed, both nationally and locally, as, in all re-

spects, to supplement and coordinate with the work of constituted public health authorities and of the medical profession.

It should be regarded as an essential principle by the Red Cross that all health work undertaken shall be carried on only with the knowledge and approval of the state department of health and of the locally constituted health authorities of county, city or town. It should be considered a primary responsibility of the division offices of the Red Cross to consult with the state department of health and of the chapters to consult with local departments of health before engaging in any new health activities and to keep such departments regularly informed of their progress and development. It is desirable, whenever possible, that the local health officer should be an active or co-opted member of each Red Cross chapter executive committee.

Essentials for Success

In view of the intimate contact between a public health program of any type and the work of the medical profession, it is recommended that chapters ask the local medical society or the local physicians as a group to nominate a doctor of their own choice to act as their representative on the Chapter Executive Committee or the Committee on Nursing Activities.

It is axiomatic that neither the nurse nor any other Red Cross worker diagnoses, prescribes, or gives medicine or surgical care except under doctor's orders.

The following principles now governing chapter procedures which relate to the medical profession are approved by us:

(1) The nursing of patients shall be carried on only under the direction of a licensed physician.

(2) In advising relative to securing medical or surgical treatment the Red Cross does not choose between individual licensed practitioners. Such choice must be left to the individual patient or to his family.

(3) The Red Cross advises with reference to securing special medical and surgical treatment only after consultation with the physician where one is available.

Chapters which employ public health nurses should request the medical society or the local physicians as a group to endorse standing orders which the nurse should follow in giving nursing care on her first visit to a patient if the patient has no doctor, or if the nurse cannot get in touch with the patient's doctor.

It is understood that such orders do not authorize a nurse to continue giving nursing care after the first visit if there is no doctor in charge, and that the nurse will make every effort to get in touch with the doctor in order to secure his specific instruction in person.

The medical society should also be asked to decide to whom the nurse shall refer indigent patients for diagnosis and treatment in the absence of a public physician for the poor; and to say what the nurse is to do if a patient having no family doctor and no knowledge of local doctors asks for suggestions as to medical care.

The success of the Red Cross health program, on a comprehensive scale, depends, first of all, in our opinion, on the appointment of a Director of Health Services of such capacity, experience and reputation as to command the respect and cooperation of public health officials and of the medical profession throughout the country. He should be provided with such expert assistance as may be necessary to guide and coordinate chapter health activities and the specific health activities listed herein, except Numbers 4, 5, 6 and 7, should be placed under his direction.

In the second place, it seems to us essential, if a comprehensive health program is to be undertaken, that it should be inaugurated with ample publicity and with the full and wholehearted support of the Central Committee and the executive authorities at Washington. Such a program can succeed only with vigorous and enthusiastic support by the central organization of the conception of a broad educational health program as one of the primary and essential objectives of the Red Cross in peacetime.

Finally, it is understood that our approval of the health program is conditioned on the fulfilment of the limiting conditions laid down above and that in approving it we assume that the authority of the official heads of the organization at Washington will be fully exercised to secure the acceptance by the chapters of these conditions.

Advantages to Be Gained

The primary incentive for undertaking a comprehensive Red Cross health program lies in the fact that the greatest present need in the field of public health is the need for educating the individual citizen and mobilizing popular support for the work of existing official and voluntary

health agencies; and in the fact that the Red Cross through its chapter organization is possessed of exactly the machinery best fitted for carrying out such tasks. Incidentally, however, we believe that the American Red Cross would itself be materially strengthened by the adoption of such a program. The power of the Red Cross for the carrying out of its beneficent ideals depends on membership, financial resources and organization. It is the belief of those who have most carefully studied the question, in many countries, that the inauguration of a definite peace-time health program is the step which will prove most effective in increasing its power along all three lines.

The National Red Cross Society should include in its permanent membership from 10 to 20 per cent of the population of the country. It is quite impossible to reach any such standard unless the members first of all receive something for their membership, and, secondly—and this is even more important—are given something practical to do for the organization of which they form a part. The instinct of service is a strong and deep one.

If we can only show to the average citizen that the burden of preventable disease is indeed a menace to the prosperity of the state, as grave as the menace of a foreign foe, we shall find ready response. The health program outlined above gives to the Red Cross member the advantage of organized instruction in the art of living which will protect him and his family from danger; and it makes an inspiring appeal to him to give his services in the task of safeguarding the community as a whole against the evils which threaten it in the form of preventable disease.

In the second place, the health program should greatly increase the financial resources of the Red Cross, not only by multiplying its membership dues, but by making it possible to secure special gifts and endowments for the specific purposes of the health campaign. The safeguarding of health has a peculiar appeal to the wealthy and public-spirited citizen; and the funds which have been obtained for specific health purposes by other organizations are merely an earnest of the potential resources which could be drawn upon for a com-

prehensive campaign against preventable disease.

Finally, the machinery necessary for the carrying out of the health program would provide the Red Cross with an ideal organization, not only for the attainment of these specific purposes, but also for the execution of the tasks of disaster relief and war-time service. The improvisation of machinery to meet an emergency is always a difficult task, but the strengthening and vitalizing of chapter organization which would result from an intensive health campaign would be turned in an instant to the special objective of disaster relief and would furnish a basis for immediate efficiency in the face of a war emergency.

For all these reasons we believe that the inception of a comprehensive health program by the American Red Cross would not only constitute a public service of the first magnitude, but would greatly strengthen the Red Cross for all the other tasks which may be before it; and we urge that such a program be undertaken, along the general lines laid down above, at the earliest possible moment.

Sewage Problems at Indianapolis

THE Report of the Board of Sanitary Commissioners of the Sanitary District of Indianapolis contains a report by Charles H. Hurd, consulting engineer, on the sewage disposal problems of the city which is of unusual general interest.

Indianapolis has a present population of nearly 350,000, and its sewage drains into White River, making it the largest city in the United States situated on a non-navigable stream. The dry weather flow of sewage is fifty million gallons per day and the stream flow varies from 175 second feet in dry periods up to several thousand second feet. In other words, at periods of minimum flow the volume of stream flow is only two and one-fourth times the volume of the sewage which enters it. The seasonal variation in total oxygen demand of the city sewage, and in the available oxygen in White River, is shown in Table I and Fig. 1. The decrease in oxygen consumed and increase in oxygen dissolved for fifty miles below Indianapolis are plotted in Fig. 2, showing the time required for natural forces to restore the river to a reasonable condition of stability. The nuisance created below Indianapolis with the full discharge of untreated

sewage flowing into the river during dry weather flow is of such character that the demand for treatment is unquestionable.

TABLE I.—SEASON VARIATION IN SUPPLY AND DEMAND FOR OXYGEN. WHITE RIVER.

	Available Oxygen		Oxygen Demand	
	Parts per million	Pounds per day	Parts per million	Pounds per day
Jan.	12.6	57,900
Feb.	12.3	65,600
Mar.	11.9	95,700	150	56,600
Apr.	10.2	68,100	158	59,000
May	8.5	25,800	164	61,200
June	7.3	18,600	187	69,800
July	6.9	18,300	178	66,500
Aug.	7.4	14,400	161	60,200
Sept.	7.9	14,410	140	52,000
Oct.	9.5	17,500	136	50,100
Nov.	11.0	53,200	142	53,000
Dec.	12.5	60,600	140	52,200

By analysis the problem of sewage treatment resolves itself into two parts. During the summer or for approximately six months in the year, complete disposal of organic solids must be made; during the balance of the year or through the period of greater dilution only such treatment may be necessary as will remove objectionable organic solids, leaving an effluent within the range of the digestive power of the river, or in other words, with the oxygen demand under

the amount of the dissolved oxygen available. From the view point of design and construction, a plant to perform the above function must be a combination of a clarifying and complete treatment system.

Based on this assumption preliminary studies were made of the efficiency of screening and sedimentation plants at various other localities and a demonstration plant combining screens and sedimentation units was finally installed. This combination in tests made in 1921 showed from 20 to 51 per cent removal of suspended solids, (averaging about 32 per cent), giving an effluent satisfactory through the period of high dilution in the river and yielding a sludge easily drained to 85 per cent moisture content.

Activated Sludge Experiments

During the year of 1921 a demonstration activated sludge plant was constructed and operated in connection with the screen and rapid sedimentation plant to determine the effectiveness of this method of treatment on Indianapolis sewage. Three complete units were installed with aeration tanks 12 feet in diameter and 15 feet high and settling tanks about one-half the capacity of the aerators.

Fig. 1.—The seasonal variation in total oxygen demand of sewage of the city of Indianapolis, and the available oxygen of White River are shown in this figure and in Table 1.

Air was supplied through filtros tile in the usual manner, provision being made for filtering and scrubbing the air to eliminate dust or particles of oil which would tend to clog the filtros plates. Both screened and unscreened sewage were run through these tanks in comparison. The former was handled much more satisfactorily. In one typical test the treatment of the screened sewage yielded an effluent with only 19 p.p.m. of suspended solids, an oxygen consumed value of 26 p.p.m. and stable for 7 days. The air supply was 1.3 cubic feet per million gallons, while the waste activated sludge produced (dry basis) was 1,152 pounds per million gallons.

Final Plans for Plant

Encouraged by the results of a small aeration tank used as a circulating unit with filtros tile arranged eccentrically to give rapid circulation by the air lifting effect, two large tanks were equipped in this manner, while another similar tank was operated in the standard form as a control unit. The filtros areas in the circulating tanks were 10 per cent and 12 per cent respectively. The conventional type of tank had 25 per cent filtros tile area. The three tanks were operated on screened sewage.

All three of these units produced an effluent of high stability. The circulating tanks showed a perceptible saving in the use of air over the standard tank operating with considerably less than one foot of air per gallon of sewage, and also having greater capacity with the same effluent standard.

From all the data available including conservative estimates of construction costs and the comparatively

low cost of fuel and power for operation, and taking into account the high degree of purification and flexibility of the plant, for conditions obtaining, upon the recommendation of its engineer, the Board of Sanitary Commissioners has authorized the construction of an activated sludge plant for the Sanitary District.

The site of the treatment plant, being on the opposite side of the river (two miles below the outfall of the main interceptor) the sewage will be carried under the river in an inverted siphon 1,000 feet long. To prevent deposits in this siphon it was deemed best to locate grit chamber on the east bank of the river immediately in front of the siphon.

The grit chambers containing the coarse bar screens are constructed with three channels, each ten feet wide and with walls ten feet high. Each channel is provided with independent gates to be used in dewatering in addition to stop planks for the regulation of flow. The completed grit chambers and sluice gates are shown in Fig. 3. A controlling gate is installed at the head of the chambers which operates as a submerged weir serving as an overflow for storm water and for rate control. Velocity through the chambers may be regulated from 7/10 to 1 foot per second.

Sixty inch cast iron pipe is used in the construction of the siphon which is laid from seven to twelve feet below the bed of the stream. From the end of the sixty inch siphon the sewage will flow through 8,000 feet of seventy-eight inch reinforced concrete conduit, which has been completed. This conduit continues in almost a direct line, is built on a grade of 0.0008 and has a capacity of 108 million gallons per day. At the point where this conduit delivers sewage into the pump well it is united with the connecting conduit from the west side interceptor which is provided with grit chambers and coarse screens of a size corresponding to the flow for that system.

More than ordinary care has been exercised in the design of plant buildings. For the most part, Spanish type of architecture has been used. The color effect is gray buff brick and terra cotta trim with green glazed tile roof construction. All

Fig. 2. Oxygen dissolved and consumed in White River below Indianapolis. In the completed process the water will return to the river in a relatively high purified state and the organic solids will be fertilized.

buildings are fire proof and the general arrangement is consistent with the use of the additional acreage, which will be a part of the city park and boulevard system.

The clarification plant for the partial removal of suspended solids comprises twelve revolving drum screens arranged with three in each channel, which are connected with the concentrate thickener tanks constructed just outside of the pumping station building. The screens are constructed entirely of brass and bronze, eight feet long and six feet in diameter and arranged to filter from the outside in, delivering the effluent through an opening at the end. In a measure the screens are self cleansing as part of the effluent passes through the down stream side of the screen removing adhered solids, and is further assisted by the rotation of the screen element through this clarified zone. No. 30 phosphor bronze wire cloth is used as the screening medium.

In order that the screens may give maximum removal it is essential that the process be carried on without the breaking up of the solid particles. For this reason the heavy concentrated sewage containing all the retained solids is conducted by gravity, to the concentrate thickeners from which the heavy sludge is continuously removed by mechanical means.

The concentrate thickener tanks are four in number, 15 feet wide at the top and approximately 120 feet long. These are equipped with slowly moving flights which will sweep the hopper bottom operating counter to the current. The return flights move with the current and at approximately the same rate with a maximum speed of seven and one-half feet per minute.

The clarified effluent may be discharged directly into the river (at times of high flow) or pumped to the aeration tanks for further treatment. In the activated sludge plant, aeration tanks are designed and being constructed of the circulating type found most advantageous at the demonstration plant. These tanks have flat bottoms, each with four channels 238 feet deep. Settling tanks for the activated sludge are of the mechanically cleaned type and conform in dimensions to the aeration tanks. The aerations tanks are designed for an average rated capacity of twenty million gallons per day per acre and the settling tanks for a maximum rate of about 1,600 gallons per day per square foot of area.

The total estimated cost of the entire project is \$2,438,000.00. Of this

Fig. 3.—Controlling gates and detritus tanks of the preliminary sewage disposal plant.

\$676,600.00 is allowed for interceptors, connecting conduits, outfalls, roads, levees and river protection; \$491,000.00 for the clarification and pumping plant, including fire screens and concentrate thickness tanks; and, \$1,270,400.00 for the main power plant with compressors for aeration, the complete activated sludge plant, the water supply and sludge dehydration.

The clarification system and main

interceptors in accordance with the construction program are to be completed and put in service in the spring of 1923 and the activated sludge plant—final purification—1924.

In the completed process the water will return to the river in a relatively high purified state and the organic solids will be fertilized; all to the betterment of public health and assisting in an important economic cycle.

A. M. A. Winter Conference

THE American Medical Association conference on medical education and public health, held in Chicago, March 5 to 7, was marked by an admirably constructive and harmonious spirit. Its program included discussions of hospital problems and of the principles underlying the relation between the physician and the public, which need not be analyzed here in detail. Under the heading of medical education, an interesting discussion centered about the Toronto plan (presented by Dr. Ryerson) for replacing the division of the medical sciences along the conventional lines of anatomy, physiology, medicine and surgery, by a classification according to the organs of the body; the first year student, for instance, learning all about the bones (anatomy, physiology, medicine, surgery, etc., of the osseous system), the second year student all

about the circulation, and so on. This is a suggestion which will not strike the public health worker with great favor since it seems likely that such a training would aggravate the tendency to look for particular diseased organs rather than to consider the health of the human body as a whole.

The last session of the conference was devoted to the problem of the training of sanitarians, with Surgeon-General Cumming in the chair. General Cumming and Dr. Draper recounted the work done by the Public Health Service since the conference of last March in collecting and disseminating information in regard to facilities for training and opportunities for trained men in the field of public health. Dr. McLaughlin outlined the steps for standardizing degrees and certificates in Public Health which have been taken by the standing committee on public health

training of the American Public Health Association. Prof. Winslow spoke of the importance of inspiring the medical school with the ideals of preventive medicine, and particularly of what has been done along this line at Yale. Dr. Haven Emerson and Dr. F. W. Sears of Syracuse discussed the extremely important problem of organizing short courses for the health officers now in the field.

Perhaps the outstanding event of the whole conference was the report before Dr. Bevan's section of a special committee on nursing education. Dr. Lovett of Boston, the chairman of this committee, presented a review of the problem and a set of recommendations which promise to prove of epoch-making importance. The conclusions of Dr. Lovett's committee were backed throughout on those of the Rockefeller Committee on Nursing Education and endorsed without qualification the development of shorter (twenty-eight months) and better courses of training for the bedside nurse, courses based on a high school diploma, freed from hospital routine and organized on a truly educational basis. It also endorsed the plan for the training and licensure of a second grade of nursing aids for the care of chronic illness and convalescence. Furthermore, Dr. Lovett recommended that definite steps should be taken for standardizing curricula and for grading training schools along the lines laid down; the work to be done by a joint committee made up of physicians appointed by the A. M. A. and of nurses appointed by the League for Nursing Education, in equal numbers, with one additional member who should be an educator but neither a doctor nor a nurse. The broad and liberal vision evidenced in this report is highly promising. It will take the joint effort of the medical and the nursing professions to place nursing education on the plane where it belongs; and Dr. Lovett's committee has presented a platform on which co-operation can be secured with honor to all concerned.

A bill concerning uniform regulation of marriage and divorce, recently introduced in the United States Senate, contains several items of interest to sanitarians. For instance, Section 4 states that no license to marry shall be issued to a person who is insane, imbecile, pauper, epileptic, feeble-minded or afflicted with tuberculosis or venereal diseases.

Cancer Death Rate is Higher

The returns complied by the Bureau of the Census show that more than seventy-six thousand deaths were due to cancer in the registration area of the United States in 1921. Assuming that the rest of the United States had as many deaths from this cause in proportion to the population, the total number of such deaths would reach 93,000 for the entire United States, while for 1920 the number is estimated at 89,000, or four thousand less than for 1921.

The trend of the cancer death rate is upward, the rate for 1921 being higher than that for any earlier year in twenty-three of the thirty-four states for which rates are shown. The cancer death rate in the registration area in 1921 was 86 per 100,000 population, against 83.4 for 1920. In comparing the death rate from cancer in one state with that in another, the Bureau uses "adjusted" rates in order to make allowance for differences in the age and the sex distribution of the population, because generally speaking, only persons in middle life and old age have cancer, so that a state with many old persons may be expected to have more deaths from cancer than a state with comparatively few old persons.

The highest "adjusted" cancer rate for 1921 is 99.6 per 100,000 popula-

tion for the state of Massachusetts, and the lowest is 47.6 for the state of South Carolina.

For a few states adjusted rates have been calculated separately for the white and colored population. In this group of states the highest adjusted cancer rate for the white population is 95.9 per 100,000 population for New York and the highest rate for the colored population is 90.6 also for New York. The lowest adjusted rate for the white population is 51.5 for Tennessee and the lowest for the colored population is 36.4 for Florida.

Summarized briefly, the adjusted rates show that the northern states have comparatively high and the southern states comparatively low cancer mortality, while there is little difference between the adjusted cancer rates of the white and colored races of the same states. In other words the white and colored races seem equally susceptible to cancer, but both races seem less susceptible in the south than in the north.

The Rockefeller Foundation has elected to its board of trustees Dr. Ray Lyman Wilbur, president of Stanford University, and William Allen White, editor, Emporia, Kansas, and to membership on the International Health Board, Dr. David L. Edsall, dean of the Harvard Medical School.

Mechanical vs. Psychic Factors in Accidents

Underwood & Underwood

Much has been said about the "personal equation" in the effort to clarify questions of culpability in serious accidents. Several states, notably Indiana, have lately advocated psychological examination of all automobilists. That mental and mechanical factors are inseparably connected was brought out in a recent case tried by Judge Joseph Chambers of Los Angeles recently. The complicated accident was re-enacted by the use of toy autos and street charts, and the enreless driver was incriminated as a result of the study. Why the laborious effort to save the child from disease and permit reckless destruction of life through preventable accident?

Illustrated Health Talks for Children

By H. E. KLEINSCHMIDT, M. D., ACTING DIRECTOR, DEPARTMENT OF MEDICAL MEASURES, AMERICAN SOCIAL HYGIENE ASSOCIATION, NEW YORK CITY.

THE writer, who is not by occupation a teacher of children, recently enjoyed the opportunity of giving a series of health talks to boys and girls ranging in age from eight to fourteen. The results of this attempt are, in his opinion, sufficient justification for presenting herewith one of the talks as a suggestion to others who may have the opportunity of teaching children, and in the hope that if there is merit in the method it may be developed by others more adept.

In all of the talks simple objects commandeered from the household, or purchased at small cost, served to stock the speaker's "bag of tricks." The fact that, in spite of his inexperience in this particular undertaking, the complete attention of the children was steadily sustained for twenty minute periods, he attributes to the inherent interest all children seem to have in the methods of the magician, be he crude or clever; or perhaps the "vicarious" restlessness of the speaker in demonstrating his objects will account for the concentration of his youthful audience.

If the method is pedagogically sound, there is no reason why almost any phase of health teaching may not be suitably illustrated in a similar manner. Since expensive equipment is not necessary such talks may be given under most modest auspices and in the remotest rural school, the only requirement being that the teacher understand the subject and that she exercise a bit of ingenuity in inventing and finding the appropriate graphic aids. A typical example of talks of this kind is talk number 6, to children and their parents on health examinations, reproduced herewith.

Until the public learns to appreciate scientific medicine, little progress can be made in combating the evils of quackery, cultism, self-treatment and health-neglect. Too many people treat their bodies, highly organized pieces of mechanism, as if they were made of imperishable stuff, resistant against all abuse, and with little attempt to conserve the precious heritage of health. When illness does come, the tendency is to experiment or listen to the advice of the most plausible advisor with a childish gullibility which is disheartening to the trained health worker.

An illustrated talk, something like the following, may perhaps tend to create a respect for the human body as a machine and to emphasize the point that a medical tyro should not be trusted to adjust that machine when perchance its functions deviate from the normal. It may serve also to impress the importance of a periodical physical examination. While designed primarily for children of middle and upper grades this talk should be of interest also to adults, especially if given to a group of parents and children, ostensibly to interest the latter.

The properties consist of: an alarm clock which has outlived its usefulness; a hammer; a screwdriver; and a pair of pliers or other tools. The alarm clock is "fixed" in advance in such a way that when the back is removed springs, pinions and wheels fly out in a most inglorious fashion.

Objective Methods

The speaker, holding up the clock, says "No household is complete without this well-known friend. It is used, I suppose, to remind boys when it is time to eat.—No?—Of course not—boys do not need that kind of reminder. Ask Dad, he knows what it is for—many a comfortable dream of his has been rudely interrupted by the over-zealous alarm clock."

"This clock of mine has been ticking merrily on for some two years, but the other day it suddenly stopped. What can be the matter? What do you advise me to do with it?" Someone suggests that it be taken to the watchmaker. This good advice is scorned, for "why should I, a practical amateur mechanic, spend good money to have it repaired? I understand machinery and have no money to waste on the watchmaker—I am going to fix it myself." The clock is vigorously thumped with the fist and then held up to the ear. No result. Very well, a harder blow with the hammer sometimes wakens the engineer inside. Bang! bang! bang! with the hammer, bang! bang! Still it refuses to go. The hammer has succeeded only in denting the sides and cracking the glass. "But we will open it and see what makes it 'not tick' as the Irishman would say." The speaker takes up various tools with a great show of craftsmanship and labors

with the clock. He is awkward, sometimes pounds his fingers or lets the clock slip out of his hands, but eventually succeeds in prying off the back cover. With a whirring rush the spring leaps forth, startling the speaker, who drops the clock, while bits of the works scatter about over the floor. (The younger children will be delighted with this bit of slap stick if it is skilfully staged.)

"Oh, what a hopeless mess—how foolish I was to meddle with something I do not understand. 'Cobbler, stick to your last' is a lesson one cannot afford to ignore." Thus the speaker goes on good humoredly to chastise himself. "Well," he says, resignedly, "it is truly a scrambled clock—let us make a new start."

Turning suddenly to the teacher, who has, without the knowledge of the audience previously agreed to be a confederate, he says, "Miss Brown will you oblige us by lending me your watch?" Of course Miss Brown is loath to do so and declines as gracefully as she can. It is patent that she does not wish to trust her watch to the speaker. After some good natured banter and a solemn promise that it will not be injured she reluctantly gives up her watch. The speaker admires it. "Ah, no wonder, what a beautiful timepiece!—presented to daughter!" (reading the engraving inside the lid) "on graduating from high school, 19—." Not a cheap watch this—an Elgin—it is a charming piece of mechanism in a beautiful case."

A dialogue ensues between the teacher and speaker in which it is brought out that the watch keeps excellent time, that she winds it regularly, handles it tenderly, etc. Once, alas, it was injured by a fall. Did she attempt to repair it? Indeed not! Carefully she carried it to a blacksmith (Miss Brown is shocked and protests instantly)—"Of course, beg pardon, she took it to a skilled watchmaker." The picturesqueness of this interesting craftsman is dilated upon if time allows. The skilled craftsman received it lovingly, as if it were an only child, and with deft hands and cunning tools restored it to its original state. "That was six years ago—and has it never been back to the watchmaker?" Oh, yes, once each year she takes it to him for examination and cleaning for, despite the fact that the

double set of lids fit with uncanny accuracy, tiny bits of dust *will* get inside and clog up the delicate works. The oil, too, becomes dried and sticky. This means friction; friction means wear, and wear means eventual destruction. "But with the excellent care Miss Brown gives her watch it will doubtless keep accurate time for many a year, and perhaps be passed on to her granddaughter when she graduates from high school," which brings an embarrassed blush to Miss Brown's smiling face.

"How many boys and girls own a watch?" Not many. "How many are going to own a watch when they are old enough to take care of one?" Every hand goes up enthusiastically. "Do you know that each of you is the custodian or caretaker right now of a wonderful piece of mechanism far more valuable, more precise, more delicate and more useful than the finest watch in the world? The human body is sometimes regarded as a machine. A watch does one thing, keeps time. An auto another—it runs. A sewing machine still another—it sews. (The children supply the answers). But how many useful things the human machine does! The children, asked to name some, begin by saying it can walk, make things with the hands, etc. They are led on to include seeing, hearing, digesting, breathing, the pumping of the blood and, last and most wonderful, thinking. "Does the machinery ever go wrong?" Unhappily yes. Fingers are cut, heads are bruised, legs are broken, the body becomes ill. "Then I suppose we tinker with the machinery just as I did when I 'fixed' the clock? We buy a bottle of pink medicine (don't know what is in it or what it will do but the label assures us it will cure whatever ails us). Or we ask a friend what cured him; or we allow a person who proclaims himself as a human repairman but who has not studied the human body long, intelligently, and diligently, to tamper with human machinery.—No. No, we cannot afford to do that. We seek out an expert, a doctor, one who, though humbly modest because of the little he knows about so sacred and complex a thing as a living breathing body, yet makes it his earnest life's work to understand some of the secrets of the mechanism of the body. To him we go for advice, and the wise physician, with his ear carefully attuned to the whisperings of Nature, tells us how best to give Nature, the real restorer, a chance to set the machinery in order again. The doctor is to the human

body what the watchmaker is to the watch."

"Keep well is better than get well. Damage once done may not always be remedied. Nature is generous in dealing with her children but sometimes the damage is so great that complete repair is impossible. Do you know that the human body is the only machine for which there are no spare parts?" Tell the story of a friend who owned a valuable Swiss watch. A certain vital part became broken. The local watchmaker could do nothing with it until he had sent to the original maker of the watch in far away Switzerland for the necessary part, and for eight weeks this friend was obliged to wait. Repeat the thought that for the human body there are no spare parts, in Switzerland or anywhere else.

All damage to the human body, except in cases of accident or certain acute diseases—most of which are now avoidable—usually takes place very slowly. And fortunately the damaging process may be discovered by one who understands the mechanism of the human body before serious harm has been done. It is the wear and tear due to neglect which most often breaks down the human machine. A bit of dust in a watch may wear down one of the smooth-moving parts of the watch. Soon the roughness of this part has its wearing effect on the part into which it fits, a phase which may be illustrated by using some of the parts of the alarm

clock. As time goes on the entire works become damaged and the watch is ruined. Just so, slight disorders of any part of the body, if neglected, have a damaging effect on other parts. Why not, as Miss Brown does with her watch, take the human machine to the master at least once a year for examination and overhauling just to be sure that all is working smoothly. An excellent idea, and to a degree that is what our school physician, ably assisted by the school nurse, is doing for us. They with their trained eyes and ears and fingers look us over once a year and tell us just what little defects need correction. Some of us are told how to eat, others are taught better posture, still others are advised to see their family physician so that a valuable machine may not suffer because of neglect.

"It is foolish to keep the mind constantly fixed on the state of one's organs, and worse yet to be ever fearful of disease. A health examination at least once a year will banish that worry. But most valuable of all is the satisfaction of knowing that our machine is in perfect running order. That alone is sufficient reward."

Monroe County (N. Y.) Tuberculosis Sanatorium has affiliated with the Rochester General Hospital to start a school for trained attendants. The course consists of thirteen months training. Graduates will be given the title "Trained Attendants."

New Health Era in Honolulu

The House of Friendliness under the auspices of the Young Women's Christian Association of Hawaii is to be credited with the first consistent effort to train the native women in first aid and in the fundamental principles of child care.

Wide World Photo

Colorado Rural Work in Tuberculosis

Rural Work of Colorado Springs Branch of the Colorado Association

BY ELOISE A. CLEVELAND, DIRECTOR OF SOCIAL SERVICE-NUTRITION DEPARTMENT, COLORADO SPRINGS BRANCH, COLORADO SPRINGS, COLO.

IN THE fall of 1921, the Colorado Springs Tuberculosis Association, with the approval of the County Superintendent of Schools, undertook the demonstration of the Modern Health Crusade in the Lewis Consolidated Schools at Monument, Colo., to find what actual results could be obtained.

The school had 170 children enrolled. Health talks were given by the representative of the Colorado Springs Tuberculosis Association before the Parent-Teacher Association and in the school. Both the Parent-Teacher Association and the school quickly responded with ideas of their own. From that first meeting until the end of the year, there were few meetings of the Parent-Teacher Association where health topics did not predominate. The School showed its interest by making the Crusade a vital part of its course, correlating it with every study.

In January, 1922, an examination was arranged through the aid of interested physicians. The parents were present, and all through the year, the defects found were being corrected. It was found that including borderline cases 75 per cent of the children were underweight. The whole school became interested in a nutrition program. Hot lunches were served for two months, \$160 being raised by the Parent-Teacher Association to furnish one hot dish daily for all the children, and six gallons of milk to furnish mid-morning and mid-afternoon lunches for those underweight. A study of food values and combinations was made in each room. This intensive work resulted in bringing all except twenty of the children to normal weight within two months.

In the physical examination, it had been found that the majority of the children in the first, second, and third grades had slight curvature of the spine, due to faulty seating. Blocks were placed under the children's feet and larger children put in the higher seats. To correct the curvature, posture drills and relaxing drills were given daily throughout the entire school.

Ten minutes are given each morning for health work. This included inspection and health talks by the teacher. Games, folk dances, health plays and stories made the work interesting to the younger children. In the high school each Friday afternoon was given to the discussion of health problems, the students having prepared papers under the guidance of their teachers. Several addresses by physicians were made before the Parent-Teacher Association and the school, in addition to those of the regular worker. The school was visited at least monthly. The principal and teachers kept in close touch with the worker by correspondence and through calls at the office. As the workers time was limited, the weighing and measuring was done by the school.

The teachers were more strict in counting chores than the Crusade required, as they demanded the performance of each chore at least five times each week.

As the Lewis Consolidated School at Monument had successfully demonstrated the results which could be attained through the Modern Health Crusade, it was decided by the Executive Committee, at the end of the year of work, to make the Crusade a permanent department of the Colorado Springs Tuberculosis Association, employing a full time worker as Director of the Crusade among the rural school children of El Paso County.

In the fall of 1922, definite plans were outlined. Dr. C. O. Giese was asked to take charge of the department. All work has been done under his supervision. The plan for the rural work follows:

(1) A complete physical examination of each rural school child in the county. Records of each examination

to be kept in the office of the Colorado Springs Tuberculosis Association and in the schools. A letter to be sent to each parent, giving results of examinations.

(2) Talks by physicians on hygiene, children's diseases, etc., at request of Parent-Teacher Associations.

(3) The establishment of the Modern Health Crusade in a limited number of consolidated schools.

(4) Contest between schools in greatest percentage of corrections both in weight and physical defects.

(5) Visit by Health Crusade worker twice a month in schools undertaken. Monthly weighing of all children in these schools.

This rural work was actually begun on November 1, when preparation for the first physical examination was started. The city worker was directed to organize this work.

It was agreed that the superintendent of county schools, should receive all applications for medical examinations from the principals of schools. These applications were then to be sent to the Colorado Springs Tuberculosis Association who would care for them in the order of dates.

All applications for the follow-up work through the Modern Health Crusade were to come from the principal and Parent-Teacher Association to this association direct.

During the months of November and December, 704 children were weighed and measured; five addresses were made to Parent-Teachers associations with a total attendance of 255; 24 Health Crusade addresses were given to teachers and children with a total attendance of 682; four school medical clinics were held with service to 384 children; and three other schools were prepared for such clinics. In November, when the El

TABLE I.—PERCENTAGES OF CHILDREN UNDERWEIGHT, NORMAL AND OVERWEIGHT IN SOME SCHOOLS IN EL PASO COUNTY, COLORADO

	Fountain	Manitou	Peyton	Edison	Harrison	Lytle
	249	125	50	133	18	33
Number in school.....	249	125	50	133	18	33
Per cent	Per cent	Per cent	Per cent	Per cent	Per cent	Per cent
7% or more underweight.....	32	37	50	10	11	85
Less than 7% underweight.....	27	31	20	..	22	29
Normal.....	37	28	26	..	66	29
Overweight.....	2	2	4

Paso County Autumn Exposition was held, space was reserved for the Association on a platform about twelve by ten feet, screened on three sides. Here posters, procured from the state office, taught lessons in hygiene and food. The central attraction was a pair of scales where large numbers of rural school children were weighed daily, while eager parents anxiously waited to know if the children were up to normal. A nutrition worker was in attendance all day to answer questions as to what should be done with children underweight. The exhibition aroused great interest. The need for this form of work as revealed by monthly weighings is shown in Table I.

The Modern Health Crusade will be confined to a small number of consolidated schools, as it is thought that the best results will be obtained through intensive work, rather than in spreading the work over a county of 2,310 square miles. The work is being done on the same lines as that done in Monument in 1922, arousing the interest of the children through health songs, poster work, games, etc., as well as in giving instruction in values of food, hygiene, and community problems.

The physical examination of rural school children was begun in El Paso County in 1921. As in all work of this kind, it has taken much time and thought to get the examination, preliminary work, and follow-up work on the most efficient working basis. The form of medical examination blank, compiled by the group of physicians undertaking the work, has eliminated much unnecessary delay and labor. This form provides for the examination of each child by six specialists, with one side of the form for a complete social history and diagnosis. In this form there is space for each specialist to make his own recommendation, showing on the same sheet all data gathered from the whole examination. On summary sheets each defect is listed and recommendations summarized, giving not only the complete physical condition of each child, but of the whole class, in a concise form. A summary sheet is made for each class in every school examined. These sheets when completed will afford the most complete picture of physical conditions among rural school children in this section. The following method of procedure is used:

On receipt of the principal's application for a physical examination, a letter is sent to him advising on what day the examination will be held, what the school will need in equipment, and stating what social

data will be needed concerning the children.

As the physician's time is most valuable, a worker is sent several days before the examination, with trained volunteers, to weigh and measure the children, compute weights, and take social histories.

This worker also prepares the school rooms to be used during the examination. These rooms are so arranged that there is no lost motion during the examination. On the morning of the examination, the child is given an examination blank, on which has been written his name, age, weight, height, percentage underweight, or overweight, and social history. He is taken to the undressing-room, where several parents are waiting. He is quickly stripped to the waist, wrapped in a sheet, and, with shoes unfastened, is passed into the adjoining room, where he is examined by the surgeon, using the school's business tables for examining tables. From here he is sent into the internist, who gives a complete chest examination. After this, he goes to the dressing room, where his clothes have been transferred to prevent any confusion between the children who have been examined and those who have not. After dressing, he goes to the nose and throat specialist, whose room is fully equipped and darkened, and last to the oculist, and nerve specialist. On finishing, his paper is handed to the person whose sole duty it is to collect these papers, and the child returns to his room. Nothing is permitted to interfere with this continuous motion which saves so much time and confusion. When necessary, dressing and undressing rooms are curtained off in the corridors. At all times the sense of modesty is respected. The children are taken by sex, beginning with the first grade, going through the grades first with the girls, and then with the boys.

At these examinations, there are usually present, two surgeons, four internists, two nose and throat specialists, one oculist, one nerve specialist, one Medical Director, who is in charge, inspecting each record as it is handed in.

Each physician brings his own checker. The worker from the Tuberculosis Association is responsible for the machinery running smoothly. She usually uses interested parents in dressing the children, in directing them in the halls, and in providing any articles, such as sheets, for the examination. The Parent-Teacher Association provides a lunch for the physicians and checkers at 12:30 p. m.

The examinations begin at 9:00 a. m., ending at 12:15 p. m.

The principal and Parent-Teacher Association always wish a report of the examination at their next meeting. The Association has always arranged for some physician to make this report, explaining the defects and recommendations.

In cases brought to the attention of the Colorado Springs Tuberculosis Association, by the Principal and the Parent-Teacher Association, where the parents are unable to finance the correction of defect, arrangements are made for the work free of charge. Laboratory tests have been made and operations performed when necessary, although parents who are able, are urged to take their children to their private physician.

Within a short time after the examination, the parent of each child receives a letter from the Association, advising him of the weight of the child, and of the recommendations of the specialists. A form letter is used which permits the filling in of individual recommendations. It is signed by the Colorado Springs Tuberculosis Association.

The value of the work is becoming recognized by the schools, who are turning to the Association for information on all health questions, such as the possibility of books used by all school children containing tuberculosis germs, and the possible impurity of the school drinking water.

It would be impossible for the Association to give the schools such efficient service if the physicians were not so keenly interested in the work. They give their time most generously. An examination is planned for one morning out of each week. In addition to this, they give much outside time in summary work and in consultation with the workers over individual cases. It is to them that the children in El Paso County will owe much of their health and happiness.

Open Air Shack at Saranac

The American Legion camp at Saranac has evolved this type of open air camp for care of soldiers convalescent from tuberculosis.

Digest of Sanitary and Hygienic Advance

Diphtheria Prevention

Zinger recommends omitting the use of the Schick test and the giving of the toxin-antitoxin injections to all children between the ages of six months and six years. The author also considers the functions of the baby health stations and the private practitioner in immunizing the pre-school child against diphtheria. (*J. A. M. A.*, Feb. 17, 1923, lxxx, 7, p. 456.)

Cost of Venereal Disease Control

The chapter on venereal disease control from the forthcoming report of the Committee on Municipal Health Department Practice of the A. P. H. A., (*J. Social Hyg.*, Jan. 1923, ix, 1 p. 27) states that the average per capita expenditure by municipal health department for venereal disease control in 38 cities is \$.021. In cities of the first population group the expenditure is \$.014; in the second group \$.024; and in the third group \$.032.

The largest per capita expenditure recorded, \$.145, is credited to San Diego.

"In the future, if municipal health departments assume responsibility for all activities of a complete program for venereal disease control . . . appropriations for venereal disease control must be considerably higher than they are at the present time."

Vital Statistics for England and Wales

A provisional statement by the Registrar General for the year 1922, gives the following death, birth, and infant mortality rates for England and Wales, London, and groups of towns.

	Birth Rate	Death Rate	Infant Mortality
England and Wales	20.6	12.9	77
105 County Boroughs and great towns incl. London.	21.5	13.0	81
155 Smaller towns	20.5	11.7	75
London	21.4	13.4	73

The birth rate given for England and Wales is the lowest recorded, except during the war years of 1915-19, while the infant mortality rate is actually the lowest on record. (*Lancet*, Jan. 27, 1923, i. 5187, p. 193.)

Industrial Diseases of the Eyes

According to Dr. T. M. Legge, H. M. Medical Inspector of Factories, amblyopia from lead poisoning, which used to be an important cause of industrial blindness, is now comparatively rare. (*Lancet*, Jan. 27, 1903, i, 5187, p. 192.) "Since 1900 lead poisoning has diminished by more than one half. In the years 1905-09 there were found twenty cases of optic neuritis from this cause; in the corresponding period, 1915-19, there were only six. These results, he says, have been largely accomplished by the advance made is locally applied exhaust ventilation, by means of fans, to remove dust and fumes at the point at which they are produced, and so prevent inhalation of them by the workers. Before the war some cases were reported of amblyopia occurring in the manufacture of explosives in which dinitrobenzol was employed, but during the war blindness from this cause does not seem to have occurred. On the whole risks of toxic amblyopia in connection with industrial processes are now fairly well guarded against."

Relapse in Malaria Produced by Ultraviolet Light

In order to test the theory that spring relapses in malaria are in part due to the effects of sunlight, Whitmore (*Amer. Jour. Trop. Med.*, vol. ii, p. 475) studied the effect of ultraviolet light upon infected canaries. He found that relapses could be produced by the rays (at 24 inches distance) in two hours with the normal bird and in fifteen minutes with the feathers of the exposed area removed. When filtered through ordinary window glass the light lost its effect.

Treatment of Chronic Typhoid Carrier

Watt reports successful treatment of a chronic fecal typhoid carrier with detoxicated vaccine. (*Lancet*, Feb. 24, 1923, i, 5191, p. 378.) Treatment at first by subcutaneous injections was later combined with oral administration which was continued after injections were stopped.

Typical *B. typhosus* at first present was replaced by an atypical organism, giving the sugar reactions but failing to agglutinate. Finally both forms disappeared and eighteen successive examinations revealed neither form.

Serum for Rocky Mountain Spotted Fever

Noguchi reports (*J. Exper. M.*, March 1, 1923, xxxvii, 3p. 383.) an unsuccessful attempt to produce from horses immune serum for Rocky Mountain spotted fever. The only animal which yields a useful serum both in potency and quantity is the rabbit. "By the early administration of such an immune serum the virus introduced into the guinea pig can be prevented from multiplying and causing fatal infection." If given during the incubation period, suppression of infection is assured; after the onset of the disease the serum has no beneficial effect.

For human cases the writer recommends testing the efficiency by intravenous injections of about 0.1 c. c. per pound of body weight.

Industrial Accident Causation

In the Industrial Fatigue Research Board's study of accident causation (Report No. 19), E. E. Osborne and Dr. H. M. Vernon state that immunity from accidents in shell factories was greatest at 67 degrees Fahrenheit, and the frequency increased at lower temperatures until at 52 degrees accidents were 35 per cent more numerous than at 67 degrees. At temperatures above 67 accidents showed a small rise in the women and men showed an increase of 39 per cent at 77 degrees. Chief controlling factors in accident causation were found to be speed of production and the psychic state of the worker. Fatigue played only a small part. This was substantiated by Professor B. Muscio in the second part of the report who found no loss of manual skill following an exercise involving moderate muscular activity carried out continuously for three and a half hours.

Protein Diet and Blood Pressure

An attempt, under hospital conditions, to determine the relation of a heavy protein diet to high blood pressure is reported by Strouse and Kelman. (*Arch. Int. Med.*, Feb. 15, 1923, xxxi, 2, p. 151.) The authors found nothing in their experiments that would lead them to believe that there was any relation between variations in blood pressure and the intake of protein food.

New Regulations for the Diploma in Public Health

"New resolutions and rules drawn up by the General Medical Council for diplomas in public health have now been embodied in the regulations for obtaining this diploma, and will come into force on January 1, 1924." (*Lancet*, Feb. 3, 1923, I, 5188, p. 240.)

The alteration creating most comment is one that stipulates that no candidate can be admitted to Part II of the examination until he can produce evidence of having been in possession of a registrable qualification in medicine, surgery, and midwifery during not less than two years, and of having completed the curriculum for the diploma extending over a period of twelve calendar months subsequent to the attainment of a registrable qualification.

This and the other changes in qualifications have aroused much discussion in the British medical press. The changes, according to most commentators, tend to discourage young medical graduates and make it difficult for the physician in general practice to qualify for the position of medical officer of health.

Experimental Epidemiology

Experimental epidemiology is a comparatively new method of scientific investigation. It promises more rapid advancement in knowledge than can be expected from the tedious process of waiting for a human epidemic, that we are all the time hoping to prevent, and then studying this under uncontrolled condition.

One of the pioneer tests of this method is being conducted by Webster at the Rockefeller Institute. He states that with "a given susceptible mouse population and a certain strain of mouse typhoid bacillus, the sporadic and epidemic prevalence of mouse typhoid are determined by the special and quantitative distribution of the bacilli." No evidence was found to substantiate the contention of other workers that there was a change in virulence during the spread of the disease. (*J. Exper. M.*, Feb. 1, 1923, xxvii, 2, p. 269.)

Physiological Effects of Tobacco

Mathien and Merklen (*C. R. Soc. de Biol.*, Lxxvii, p. 879, 1923) report that exposure to cigarette smoke markedly prolongs the time necessary for white mice to find their way out of a labyrinth.

Testing Shaving Brushes for Anthrax

According to Knott (*Lancet*, Feb. 3, 1923, i, 5188, p. 227) the process of fixing the stump hairs of shaving brushes with a hot glue-like substance often effectively sterilizes the portions of the hair so fixed.

These observations were reported in view of the fact that an idea appears to be prevalent that the correct way to examine a shaving brush bacteriologically is to seek for anthrax in the stump. "The presence of the organism in this site is admittedly almost conclusive evidence of the manufacturer's use of infected hair, but where the stump does not contain anthrax, and the free hairs do, it cannot with equal certainty be assumed that the hair originally employed was not anthrax infected."

Zinc Poisoning

In a large institution near London four hundred persons were served apples that had been stewed in galvanized iron containers. "Within a few minutes more than two hundred of those who partook of the stew complained of dizziness, sickness, or feeling of sickness, colic, and tightness in the throat. There was some diarrhea but no double vision." Doses of bismuth and chalk mixture were administered. Only ten of the persons affected appeared to be seriously ill and all were able to carry out their ordinary work the next day.

Chemical examination showed that the apples contained 7 gr. of zinc, expressed as zinc oxid, per pound, this being equivalent to 25 gr. of hydrated zinc sulphate per pound. (*Lancet*, Feb. 3, 1923, i, 5188, p. 242.)

Regulating the Use of White Lead Paint

"A bill is being prepared by the Belgian Ministry of Labor which will prohibit the sale of white lead under certain conditions, determined in accordance with the conclusions reached at the Third International Labor Conference of the League of Nations. The draft convention adopted at this conference prohibited the use of white lead and sulphate of lead in the internal painting of buildings, with certain exceptions, six years from the closure of the Conference. The Municipal Council of Liege has adopted resolutions prohibiting the use of white lead in inside and outside painting work done for the municipality." (*Lancet*, Jan. 27, 1923, i, 5187, p. 214.)

Tests for Lead Poisoning

In discussing the need for an early diagnostic sign for lead poisoning Craik states (*Brit. M. J.*, Jan. 20, 1923, 3288, p. 103) that in thirty cases of all kinds he has seen wrist-drop only once. He says also that "in the absence of serious anemia, punctate basophilia is more likely to be caused by lead than anything else," and suggests "that diagnosis should depend not on gross signs, but on appreciation of suspicious symptoms and investigation of blood and urine. Whereas examination of the urine is a tedious process, the blood film is quick, easy, and almost as reliable." Both signs disappear about the same time.

The author divided cases of lead poisoning in four groups: (1) Industrial, invariably detected by experienced medical men at the works; (2) general practice cases, mainly occupational among painters, plumbers, etc.; (3) criminal, diachylon taken with the intention of producing abortion; (4) domestic, resulting from the contamination of food and drink. Occupational cases among painters seem to be increasing, largely as a result of the use of dry sandpapering. Craik states that he has known of a healthy man who contracted a case of acute plumbism in this way in a period of three weeks.

Vaccination for Postal Employees

"The Postmaster General has arranged for the entire personnel of the postal system, numbering 333,000 employees, to be given free vaccination against smallpox and typhoid and paratyphoid fever. The Secretary of the Treasury has authorized all stations of the U. S. Public Health Service throughout the country to accommodate postal workers on their request. It is estimated that 90 per cent of the railway mail service, which has 23,000 members, have been vaccinated." (*Monthly Digest*, N. H. C., Feb. 1923, iii, 2.)

Relationships of Vaccine Virus

Von Heelsbergen in a recent communication (*Centr. f. Bakt. Orig. Bd.* 89, p. 173) maintains the identity of the viruses of variola, vaccinia and spontaneous cow-pox with that of *stomatitis pustulosa contagiosa equi*, which in turn he believes to be closely related to the viruses of fowl pox and fowl diphtheria.

Light Waves in Relation to Rickets

Recent investigation has established the fact that white rats can be regularly protected against rickets by means of sunlight or artificial rays produced by the mercury vapor quartz or carbon arc lamp. Alfred F. Hess and Mildred Weinstock, New York, (*Journal A. M. A., March 10, 1923*) have attempted a closer analysis of the spectrum in order to ascertain more precisely which waves exert this remarkable protective action. These experiments showed that in order to be of value in rickets, ultraviolet waves must have a wave length not longer than 302 or possibly 313 millimicrons. This renders light that has passed through ordinary window glass of no therapeutic value in this disorder. The experiments serve to emphasize the remarkable specificity of wave lengths of light in relation to ricket. Wave of 324 millimicrons in length have little or no value in protecting against rickets, and waves of 302 millimicrons are of great value in this respect. This signifies that a difference of about thirty millionths of a millimeter in wave length suffices to render ultraviolet light effective or ineffective. The experiments also indicate that the rays do not have to impinge directly on the surface of the skin. Clothing must be regarded as other filters which screen the effective rays, namely, according to their texture or thickness. Furthermore, a direct quantitative relationship exists between the nature of the material and the duration of exposure to sun's rays or artificial sources of light. Black clothing will absorb more of the effective ultraviolet rays than similar white material. The spectrum would seem to contain not only rays which can prevent or cure rickets, but also longer rays which are able to neutralize or inhibit the effect of these beneficial radiations. This phenomenon points to the need and the value of an analysis of rays employed in heliotherapy in rickets, tuberculosis, and other diseases. It would seem to indicate that this valuable therapeutic agent will be used with the employment of filters to absorb radiations which may be not only ineffective but also disturbing.

Labor Laws in the U. S.

A convenient compilation and comparison of the provisions of labor laws in the United States has been made by Hookstadt. (*Monthly Labor Rev., Jan. 1923, xvi, v, p. 158.*)

Theory of Activated Sludge

Bushwell and Long support the biological in preference to the mechanical theory regarding the nature of the activated sludge process. (*Eng. News-Record, Jan. 18, 1923, 90, 3, p. 119.*) One serious objection to the mechanical or colloidal theory, which assumes absorption of the colloidal dispersed matter by the sludge present, is, that as far as the authors have been able to determine, both the colloidal particles in the sewage and the activated sludge particles are negatively charged. They present a table based on a microbiological study of activated sludge showing that as the process develops there seems to be a succession or addition of forms beginning with a predominance of the minute flagellates and ciliates. Following stages are characterized by Peritrichs, Holotrichs, and Heterotrichs; zoögelic masses of the Chlamydo bacteriaceae and Nematodes; and Polytrichs.

The authors propose the following statement of the theory of activated sludge:

Activated-sludge flocs are composed of a synthetic gelatinous matrix, similar to that of Nostoc or Merismopedia, in which filamentous and unicellular bacteria are embedded and on which various protozoa and some metazoa crawl and feed. The purification is accomplished by digestion and assimilation, by organisms of the organic matter in the sewage and its resynthesis into the living material of the flocs. This process changes organic matter from colloidal and dissolved state of dispersion to a state in which it will settle out.

Sewage Treatment in England

A series of three articles in the *Engineering News-Record* (February, 1923, xc., Nos. 5, 6, and 7) deal with problems of administration and policy regarding sewage treatment in England, the status of older types of treatment, and the outlook for the activated sludge method. These papers provide a brief and up-to-date account of English procedure relating to sewage, its treatment, and disposal.

Analysis of Cod Liver Oil

In search for that constituent of cod liver oil which influence the mineral metabolism, Zucker has succeeded in producing a preparation which after a dilution of 1:1000 is as active in the treatment of rickets as the original cod liver oil. (*Proc. Soc. Exper. Biol. & Med., 1922, xx, 3, p. 136.*)

Dewatering Sludge

The use of a 36 inch Oliver vacuum filter for dewatering sludge is reported by Hatton. (*Eng. News-Record, Feb. 1, 1923, xc, 5, p. 203.*) The experiment shows "that when the sludge was properly conditioned by raising its temperature before reaching the filter from its normal (whatever that might be) to a point from 120 to 180 degrees F. and keeping the pH value within the limits of 3.3, to 4 by means of sulphuric acid the filter would produce about 65 pounds of sludge per twenty-four hours per square foot of filter cloth surface, reducing the moisture content from 99 to 80 per cent, and that it would do this all the time regardless of the character of the rawsludge."

Administration of Health Departments

The chapter from the forthcoming Report of the Committee on Municipal Health Department Practice, dealing with the administration of health departments has been printed in the *American Journal of Public Health*, (March, 1923, xiii, 3, p. 163.)

Vitamines in Ice Cream

In a study of the vitamin content of ice cream by A. H. Smith (*J. A. M. A., Dec. 30, 1922, lxxix, 27 p. 2221.*) the cream was tested for accessory food factors before freezing and the same tests (with white rats) repeated on the same mixture after it had been frozen. The results indicate that freezing had no noteworthy effect on the content of vitamin A and vitamin B. The cream made from pasteurized products was found to have no significant quantity of vitamin C.

Etiology of Pellagra

Jobling and Arnold (*J. A. M. A., Feb. 10, 1923, lxxx, 6, p. 365*) report isolating from the feces of pellagra patients a fungus-producing, fluorescent substances. Fifty nonpellagrous persons were studied and in no instance was this fungus recovered from the feces. This fungus apparently belongs to the *Aspergillus glaucus-repens* group. Mice inoculated with the fluorescent substance and exposed to the light "soon developed edema and reddening of the ears, and swelling and edema of the eyelids."

The authors state that it is not their "desire to claim or even to suggest" that they have discovered the cause of pellagra. Their findings are of some interest, however.

The Germ of Influenza

THE results of the bacteriological studies which were carried out during the height of the influenza pandemic of 1918 were profoundly disconcerting. We found that what we thought we knew about the part played by the Pfeiffer bacillus was erroneous. We learned that this organism, with the Pneumococci and the Streptococci, was of importance as a secondary invader; but it became increasingly clear that the primary causative organism which produced epidemic influenza and opened the road for their lethal activity was more elusive than ever. Claims in regard to the part played by a filtrable virus and by globoid bodies reported from England¹ were not convincing and it appeared that another world outbreak of this disease might find us as unprepared as did the last.

Meanwhile, however, there was being conducted at the Rockefeller Institute a series of investigations, by Olitsky and Gates, which have step by step aroused the conviction that a light has dawned which is not likely to be wholly extinguished by the mists of criticism. These investigators have shown admirable scientific caution in in-

terpreting their results. In their most recent communication² they say that to claim the organism they have studied "to be the bacterial incitant of epidemic influenza" "does not seem desirable." "It has seemed wiser, therefore, merely to report the experimental facts, and to defer decision of the precise relation which *Bacterium pneumosintes* bears to epidemic influenza until further experience is obtained."

Yet the experimental facts recited are full of significance. Olitsky and Gates have cultivated, by the Smith-Noguchi method, globoid bodies, of a filtrable nature, which they believe produce in rabbits the typical blood picture of influenza with a definite and characteristic injury to the lung tissue increasing specifically susceptibility to secondary invasion by other organisms. The blood serum of rabbits infected with this organism was found to contain specific antibodies against the inciting cause. Similar antibodies were found in the serum of human beings who had recovered from influenza but not in the blood of control individuals. Vaccination with killed cultures produces in the human subject the specific agglutinins active against *Bacterium pneumosintes*.

2. Olitsky, P. K., and Gates, F. L.: *Science*, N. S., lvii, Feb. 9, 1923, 159.

3. Olitsky, P. K., and Gates, F. L.: *Jour. Exper. Med.*, 1921, xxxiii, 125, 361, 373 and 713; 1921, xxxiv, 1; 1922, xxxv, 1, 553 and 813; 1922, xxxvi, 685.

The chain of evidence is surely a suggestive one. To the name given the new organism, bacteriological taxonomists will object, for it certainly does not belong to the genus, *Bacterium*, as now generally recognized. This is a very minor point, however. The essential findings have been recently confirmed by Lister in South Africa⁴. If other workers can find this organism, and, above all, if the disease can be produced by its use in the human subject—a step not taken by Olitsky and Gates—one of the most brilliant victories in the history of medical science will have been achieved.

Pay Clinics and Medical Costs

THE initiation of pay clinics some years ago at the Boston Dispensary, and their more recent development in New York City, Cleveland, Chicago, and elsewhere, have been called to more general attention by the transformation last year of the teaching dispensary of Cornell University Medical College into a pay clinic, and public response to this experiment.

The pay clinic differs from the ordinary out-patient clinic in that fees of more than nominal amount are charged—usually approximating the cost of service—and in that the medical staff is salaried. Such clinics aim to reach self-supporting individuals and families of moderate means who cannot pay for expert medical care, but who do not wish to accept charity, either from individual doctors or from institutions. Two fundamental questions are thus raised: Is it the duty and function of an organized medical institution to practice medicine, as distinguished from performing a charitable service? Can the medical service rendered patients at such an institution be made substantially better than that which they could secure in the private offices of physicians at rates which they can pay?

From the standpoint of the general public, the center of interest is largely in the second question. It would be well if considerable study were devoted by both medical and lay groups to matters of fact involved in this problem. Very little information is available as to actual cost at private rates of the treatment of such ambulatory diseases as come to out-patient clinics.

The total cost of treatment of a disease throughout its course, not merely the cost per visit to the doctor's office, is the vital element which must be considered by the family from whose annual budget the expenditure must be made. It is likewise essential to know the relative proportions in the population of those groups whose incomes and family responsibilities do not

enable them, without trenching upon shelter, food, clothing, and other necessities of life, to meet this expense for adequate treatment. The problem is complex, and each community and each part of the country will show varying proportions of the different economic groups, as well as divergencies in medical fee rates and in extent of existing hospital and clinic facilities. Any answer to the question of the extent of the need for pay clinics invites the attention of economists and statisticians, as well as of medical men and public health officials. Broad and careful study is needed of the types and costs of medical treatment, and their relation to the means of various groups in the population.

Paternalism in Preventing Disease

THE county health officer system in Vermont has been for some years an outstanding example of the best public health practice in this country and it is with deep regret that we learn of the wiping out of this excellent system by the 1923 legislature. Personal grievances and a jealous parochialism on the part of certain small town legislators are responsible for this unfortunate action, which puts the public health campaign in Vermont back for some fifteen years. Under the old plan the rural districts of Vermont enjoyed the services of a group of excellent, well trained health specialists but in the future these county health officers will be replaced by town officials appointed by the selectmen. The feebleness of the safeguards thus provided may be imagined from the fact that there are 102 towns in the state which are lacking even a physician.

In considering the probable effects of such a reaction against "paternalism" one is reminded of a passage in an address by Royal Meeker, recently appointed Commissioner of Labor for the State of Pennsylvania, in which he discusses the ideal of an "independent and self-reliant super-race of tuberculous, rheumatic, and malarial cripples, tottering unsocialistically along the socialized highways, reclining self-reliantly upon the communal benches of the public parks and staring belligerently at the communal trees, flowers and shrubbery, enjoying defiantly the social light of the great unsocialized sun, drinking individualistically the socialized water bubbling from the public fountain, in adversity even eating privately the communistic bread provided in the community almshouses, and, at last going expensively to rest, independently and self-reliantly, in a socialized or mutualized graveyard full of little individualistic slabs erected to the memory of the independent and self-reliant dead.

4. Lister, S.: So. African Med. Rec., Nov., 1922.

Nursing Education and Physicians

A SOMEWHAT vehement attack on the nursing profession in the current issue of the *Medical Review of Reviews* would not be particularly deserving of attention had advance sheets not been released to the daily press with the avowed intention of starting a campaign "to restore the mental equilibrium of the nurse and to put her in her rightful place in the shade." In this article all the misdeeds of the few, and there are some dregs in every profession, are attributed to the many; but perhaps the most significant thing is the author's conception of a nurse, that of an obedient and agreeable fifteen dollar a week servant who can be taught to read a thermometer and count a pulse. It always seems to the public health worker somewhat absurd that this sort of idea should survive. To quote from the recent report of the Rockefeller Committee on Nursing Education, "We have sought during the last twenty years for a missionary to carry the message of health into each individual home; and in America we have found this messenger of health in the public health nurse." Furthermore, as the report says later on; "That an improvement in quality, as well as an increase in the number of public health nurses is fundamental to the complete success of the public health movement, is a point on which the Committee on Nursing Education found competent authorities to be agreed."

We are not particularly concerned in regard to any harmful influence which such attacks as that in the *Medical Review of Reviews* may have on nursing or nursing education. The public is coming to understand these matters pretty well and any such effect is likely to be negligible. What we are concerned about is the possible reaction against the medical profession which is likely to follow exhibitions of this kind; and yet such a reaction would be quite as unjust in one direction as the *Review of Reviews* article in another. The real leaders of the medical profession include Dr. Welch and Dr. Biggs, Dr. Holt, Dr. Connor, Dr. Edsall, Dr. Winford Smith and Dr. Parnall, who signed the Report of the Rockefeller Committee and have always generously and far-sightedly devoted their time and energy to the upbuilding of the highest standards of nursing education. They include such men as Dr. Robert W. Lovett who, as chairman of a special committee on nursing education and service, made a splendidly statesman-like report at the A. M. A. Congress on Medical Education in Chicago last month and recommended the cooperation of physicians and nurses in the standardization and improvement of nursing education. This is the real voice of the medi-

cal profession, the voice which we have all learned to honor and respect. The physician who is out "to put the nurse in her place" is merely a small-minded individual who has strayed by mistake into a noble calling.

More Twilight Zones in Public Health

THE public health campaign is suffering a little from the handicap of too much popularity. There is a general tendency to leap on to the band wagon which is at times a trifle embarrassing to the original occupants.

In many states and many cities educational authorities are quite naturally seeking not only to expand their activities in the field of medical school inspection, but to extend their supervision downward to the protection of the pre-school child. There are strong arguments in favor of a close correlation of the general campaign against tuberculosis, or against mental disease, with the respective state and county institutions which furnish domiciliary care for these disorders; and such institutions are frequently operated by special commissions rather than by state departments of health. In several states special commissions have been created, outside the state department of health, to deal with the broad problems of stream pollution; and it is quite obvious that such problems do involve certain interests other than those of health protection.

On the other hand, it seems clear that if the health of infants is to be in charge of a special child welfare department, the health of school children under the board of education, the health of factory workers under a labor board, the campaign against tuberculosis in the hands of a state tuberculosis commission, the campaign against mental disease in the hands of a commission for mental disorders, the principal problems of sanitation in the hands of a river conservancy board, the control of milk supply in the hands of a special milk board or a state department of agriculture, there is very little left for the health workers of the community to do, except perhaps to control acute epidemic disease, a function which no one else has yet shown a tendency to covet.

The problem involved in the administrative organization of the public health campaign are highly complex ones and demand a high degree of statesmanship for their solution. There will always be the tendency to create *ad hoc* authorities for dealing with particular fields of preventive medicine and there are often strong arguments in favor of such a step. Yet after all the individual who passes through infancy and childhood and through factory life is one individual all the time

The problems of protecting his health are interlocking problems, as is evidenced by the tendency for child welfare work and tuberculosis work to expand until they include the whole field of public health. There is a real danger in too much diffusion of authority, in undue specialization, and in the organization of staffs of health workers under authorities whose main interest is not health interest and whose knowledge of health problems can not always be relied upon to produce an atmosphere conducive to the most effective service.

Tuberculosis in Industry and the General Tuberculosis Rate

THAT certain factors have been favorably affecting the death rate from tuberculosis is evident, for the mortality rate from this disease continues to decrease each year. Many different opinions are put forth as the reason for this remarkable decline and although it is a rather difficult and perhaps impossible matter to ascribe the effect to one cause we may do well by saying that in all probability many concurrent causes have been working together to produce this most welcome result¹. The generally favorable trend of the tuberculosis death rate must not however blind us to the fact that there is one field at least in which a great deal of work still remains to be done.

Industry, either directly or indirectly, contributes greatly to the mortality from tuberculosis. It is only necessary to glance at a table showing the mortality from this disease among males and females to be brought to a full realization of the fact that the excess death rate of males over females corresponds to the working age period of the industrial male population. And special studies have clearly shown that we may truly charge industry and industrial conditions with playing a leading rôle in fixing the tuberculosis rate of a large portion of the employed population.

Many industrial factors have been brought forward as the cause for the high tuberculosis rate in industry. Among these may be mentioned fatigue, posture, and poor ventilation but probably the one of most importance is atmospheric dust. A comprehensive American report on the mortality from respiratory diseases, published some four

years ago², occupations which were the chief offenders in contributing most largely to the mortality from tuberculosis. Since this time two other statistical studies have been published; of a more intensive type. In an investigation of the mortality from tuberculosis among polishers and grinders in an axe factory³ it was clearly brought out that the death rate from pulmonary tuberculosis for the years 1900-19 was 19.0 per 1000 as compared with a rate of 1.7 for the male population of the state of Connecticut. The most recent contribution⁴ which was originally undertaken in behalf of a committee appointed by the National Tuberculosis Association, was made among the workers in the granite stone industry of Barre, Vermont, and deals in detail with the environmental conditions under which the workers of the district live as well as with their anthropometric status. In spite of the fact that conditions under which these people live are far above the average and that the anthropometric records show them to be of superior physique, they suffered from a tuberculosis death rate of 4.3 per one thousand in the years 1895 to 1899, and this has increased to 10.6 per one thousand for the years 1915-1918. It is clear then that, although the general mortality from tuberculosis is on the decline, there is one industry, and study would probably reveal others, in which the mortality rate is not on the decline but rather on the incline.

Endemic Amebic Dysentery—The Extent of this Infection

THE recent report of apparently indigenous cases of amebic dysentery in Connecticut¹ calls attention once more to the question of the extent of infection with *Endamoeba dysenteriae* in the northern United States. Kofoid and his co-workers² have pointed out the frequency with which this protozoön can be isolated from the stools in members of military units not suffering from clinical dysentery. At the New York Debarkation Hospital, of the men examined who had seen overseas service 13 per cent, and of men who had not been abroad 4 per cent, gave positive results when examined for this parasite. More exhaustive studies, involving repeated stool examinations, made at Berkeley, Cal., on similar groups of soldiers gave the astonishing figures of 67 per cent and 26 per cent, for overseas and home contingents respectively. The groups examined in these studies were not typical of the

army population as a whole presumably they were made up of men invalidated for some cause or other. It would seem, however, that infection with amebic dysentery must, since the war at least, be far more widespread than has been suspected. It will be wise to be on the lookout for this disease and to secure stool examinations in any case presenting suspicious symptoms.

The Standardization of Railway Quarantine

FROM time immemorial, disease has followed the paths of travel. Plague traversed the caravan routes and dogged the steps of the Crusaders returning from the Holy Land. The development of modes of rapid inter-communication, by land, by water, and by air have in themselves only served to multiply our dangers and to facilitate the spread of infection at still swifter and more alarming rate.

Modern public health science is, however, awake to such dangers. The Bureau of Epidemic Intelligence of the Health Section of the League of Nations, for the first time in history, promises to give us the reliable information necessary for the most effective maritime quarantine; and recent studies of the United States Public Health Service are likely to lead to substantial improvements in the fumigation of ships.¹ The problems of railway quarantine are in some respects far more difficult; but here, too, substantial progress has been made as is set forth in an admirable recent bulletin by Dr. T. R. Crowder.²

A Standard Railway Sanitary Code, approved in May, 1920, by the Conference of State and Provincial Health Officers, and later by the Public Health Service, has now been officially adopted by twenty states and in essence its provisions are incorporated in the last revision of the Interstate Quarantine Regulations issued in May, 1921. By these regulations the transportation on railway trains of cases of plague, cholera, yellow fever, typhus fever, and smallpox is wholly prohibited and other communicable diseases are subject to rigid supervision. In the case of the diseases transmitted by the secretions of the respiratory tract³ it is, for instance, provided that persons affected with such disorders must be placed in a compartment separate from other passengers and must be accompanied by a properly qualified nurse or other attendant who shall comply with the provisions of the following regulations:

(a) Communication with the compartment in which the patient is traveling shall be restricted to the minimum consistent with the proper care and safety of the patient.

(b) All dishes and utensils used by the patient shall be placed in a 5 per cent solution of carbolic acid or other fluid of equivalent disinfecting value for at least one hour after they have been used and before being allowed to leave the compartment.

(c) All sputum and nasal discharges from the patient shall be received in gauze or paper, which shall be deposited in a paper bag or in a closed vessel and shall be destroyed by burning.

(d) Said nurse or attendant shall, after performing any service to the patient, at once cleanse the hands by washing them in a 2 per cent solution of carbolic acid or other fluid of equivalent disinfecting value.

Similarly effective regulations apply to the intestinal diseases, typhoid fever, paratyphoid fevers and dysentery.

The general dissemination, among physicians and among the laity, of information in regard to these standard regulations would go far toward securing the compliance with their provisions which is so clearly essential for the public safety.

Health Trends in Massachusetts

THE last annual report of the Department of Health of Massachusetts reflects in an interesting way the general trends of public health work as they manifest themselves in the commonwealth which for over sixty years has played a pioneer part in the field of public health.

The progress of sanitary science is well indicated by the fact that in the year 1921 there was but a single epidemic of any magnitude, an outbreak of typhoid fever with 129 cases and seven deaths apparently transmitted by unpasteurized milk. Diphtheria, however, continues to be a serious problem and the popularization of the Schick test is urged as one of the most essential points in the immediate public health campaign.

A particularly interesting feature of this report is a four-page bibliography of papers written by members of the State Department of Health during the year, a reminder that the better health departments are in increasing degree becoming institutions for the advancement and dissemination of knowledge and not merely for the administrative execution of the laws.

A Correction

Many readers of THE NATION'S HEALTH have noticed, as the editors have noticed, with contrite regret, that the statistics for the mortality of New York City in the leading editorial for March were headed "Deaths per 100,000" instead of "Deaths per 1,000" which was what they actually and obviously are.

1. See Public Health Reports for Nov. 3 and for Nov. 24, 1922.
2. Communicable Diseases and Travel. Public Health Bulletin No. 129, U. S. P. H. S.

3. Diphtheria, measles, scarlet fever, epidemic cerebrospinal meningitis, anterior poliomyelitis, mumps, whooping cough, influenza, pneumonia, epidemic encephalitis, septic sore throat, rubella or chicken pox, or any person known to be a carrier of these diseases.

HEALTH IN INDUSTRY

*Problems Concerning Factory Sanitation,
Industrial Medicine, and the Health and
Efficiency of the Industrial Worker*

Health of New Bedford Child Laborers

BY HUGH GRANT ROWELL, M.D., DIRECTOR OF HEALTH AND HYGIENE, NEW BEDFORD SCHOOL DEPARTMENT, NEW BEDFORD, MASS.

MANY articles have appeared recently regarding the dangers to the future of the race if the policy of permitting children of fourteen to sixteen to perform certain tasks is continued. In this connection the point is frequently made, perhaps at times not without justification, that examinations for working certificates by such children are most cursory, in fact, done with exceeding carelessness. New Bedford and Fall River are constantly mentioned as cities in which the number of laboring children is large and I am sure an explanation of the system I have installed for handling such a situation will prove of some interest and value.

At the outset let me state that I am not as yet convinced of the actual damage done to these children by permitting them to go to work, provided the control of the whole matter is in suitable hands. I hope in the near future to show some figures which will prove this idea, but the series is not yet large enough to warrant publication.

Before beginning directly on the children of this age, we must consider whether any health foundation has been laid in the early years of school and in New Bedford we find the beginning of school health work in 1910. In 1916 more time was devoted to this phase of education, and dental clinics instituted. Since that time studies of posture, elimination of dust hazards—as from chalk—lighting studies, and a sound system of school nursing have been a few of the activities. School clinics, at first a necessity, were later absorbed by the out-

Work, per se, need not be regarded as harmful to the child. Under given conditions the yellow "Promise of Employment" card may even constitute a safeguard, assuring that the labor of children between the ages of fourteen and sixteen shall be restricted to approved tasks, guaranteeing the child a certain quality of employer.

The system that now obtains in New Bedford protects child laborers by periodical physical examination, correction of physical defects, and, through the continuation school, provides for cumulative health record and supervision of progress both in mental and physical development.

patient department of the local hospital. Health habits have been taught both as such and as subject matter in other courses, as in the making of health posters in drawing courses. Weighing and measuring of pupils were encouraged and many schools established funds and bought the necessary scales. This year all schools use scales. Close affiliation with a splendid tuberculosis clinic locally resulted in the establishment of fresh air classes and these relations at present permit the services of a chest expert in any cases which appear to need such attention. Experience with part-time medical inspection proved neither better nor worse than

elsewhere. Gradually a desire for a full-time medical director arose and this year has seen its fulfillment. Conditions previous to employment are probably as favorable locally as is possible, in view of the economic status of the group, a factor which invariably influences the value of any type of health work. To advise certain innovations in diet is one thing, but there must be funds to carry out such advice.

Our general plan of handling these children is this—a definite office hour has been established daily except Sunday, at a time apparently the most convenient for all concerned. With rare exceptions, this hour is strictly kept. On arrival the children present the necessary birth certificate and school record, with yellow "Promise of Employment" card. A form known as Form M, provided by the State Bureau of Labor and Industries, is partially filled out by the clerk who then sends the child upstairs to the doctor's offices. These consist of a large hall in which the eye and ear tests are done and which, unfortunately, must also serve as a waiting-room. In practice, however, this is not as serious a difficulty as might be expected, since one rapidly learns methods of weeding out the child who learns the eye chart. An examining room, with three curtained dressing rooms opening into it, provided with excellent light, and with a sink which may be used for laboratory purposes, permits careful examinations yet avoids delays of waiting for the child to prepare for inspection.

On arrival the child presents the

cards, including a cumulative health record installed this year and which contains a record of each examination and the extent of the same, this being curtailed by the lack of right of the examiner to remove clothing from a school child. In many cases permission for a complete examination has been obtained and if so, this is on the record. A good past history of common diseases, eyes and ears, height and weight, defects and treatment, is all available on this card and at once gives the examiner a fair idea of what may be expected.

The eyes and ears are first tested, then the head, nose, throat, and teeth are inspected and findings noted. Advice is given regarding the necessity of correcting such defects as are found.

From now on the procedure differs, depending on whether the child is male or female.

Assuming it is a boy, he is sent into the dressing-room and told to strip to the waist. He is then given a good chest examination, and any orthopedic defects noted. The presence or absence of hernia is now determined. Provided he has satisfactorily met all requirements, is within ten per cent of the Wood weight tables, (which are framed on the wall) and his general history is good, he is passed for his job.

If the candidate is a girl, we must make certain concessions to this particular age and, while scientifically it may be wrong, it is unwise to request a girl of this age to remove her waist, even with a nurse present and conditions made as ideal as possible, because the public has not yet been educated up to the idea, and the disfavor with which a more radical type of examination is met in these cases might prove the undoing of work which will probably later be considered in a different light. Therefore the girls are examined as well as possible, removing only coats, etc., the examination being made through the waist. I do not believe this method satisfactory but it is better than nothing and should we have reason to require more adequate examination in special cases we can of course demand it. A nurse is always present at any examination of a girl.

A certain percentage of children will be found unsuitable for work, especially in the cotton mills, and the greatest difficulty is from defective eyesight. If the defect is not over 20/30 in one eye and 20/40 in the other, the child is allowed to go to work on a provisional certificate, be-

ing given till a week from the coming Saturday to have the eyes corrected and return for reexamination and unconditional certificate. These cases are checked by a follow-up system if they do not report. The whole proposition is carefully explained as a protection to them from danger and meets good response. No child blind in one eye or whose vision can not be corrected to normal or nearly so, is permitted to work on any job near machinery and in the continuation school which the child attends certain hours per week, similar precautions are observed.

Children with hernias are rare. They are kept from work which requires lifting, and operation is suggested.

Cases of former chest diseases, such as arrested tuberculosis are frequently referred to the Tuberculosis Clinic for opinion since in many instances they have been patients there. It is interesting to note that in view of local experience they do not seem to believe work in the cotton mills, with the exception of a few jobs, will harm the lung, in spite of certain popular beliefs. Such cases are carefully watched and given thorough re-examinations at each change of work.

Other defects are treated as indicated.

The Child with Defects

The problem of what to do with the children who must be turned down and who must find work is partly met through cooperation of local clubs and firms, certain of whom permit us to refer boys to them under these conditions.

So much for the first examination. The child goes to work and at the same time attends certain sessions in the continuation school. Here we have just introduced health work. A nurse, previously on my staff, has been transferred and records of weights and heights will be kept hereafter. She will be supplied with a list of minor defects found in the examinations and part of her work will be to assist in remedying them. A new course in home nursing and in infant hygiene is beginning and instruction in personal hygiene will likewise be taught. Thus the health work follows the child through these two years.

One important policy in continuation schools is to encourage return to school for all children who have begun to be sorry they did not continue their education, and thus the child is often brought back to the school health system.

Many of the children do not, for various reasons, hold their jobs for a great length of time. At each change of job they returned to the office for re-examination. Just how extensive this examination is depends on certain findings. In all cases the eye, ears, height, weight, throat, and teeth are examined. Should the record of other examinations, kept on file in the office, and always examined at each reappearance of the child, prove that weight was increasing and history prove good health, the chest would not be re-examined usually. However should there be the slightest indication for another examination, it would be carefully done. The reason for not doing a routine examination each time is that each child must be treated as an individual case and we must admit that frequent inspection is resented, especially if, as is often the case, an interval of only two to four weeks has elapsed. The tendency in this office is said to be to repeat examinations too often, which I cannot regard as an adverse criticism.

Nothing has been said so far about the mentally deficient child. Here, we find he almost steers himself. Few apply for work in the mills, seeking usually the jobs that require strength rather than mental development. Often they seem to be a somewhat restless type of labor and do not remain particularly long on any work. We have them fairly well sorted out in the school, having the advantages of our own full-time psychologist in the department, and certain classes for special instruction when indicated, so that the school record usually tells us what the mentality of the candidate for a working certificate may be.

When I speak of the system of this office, it is safe to call it the New Bedford system, since less than 1 per cent of the children go to private physicians for working certificates. From August 1 to January 1, 1925 cases were examined, some of whom came in several times, so that the actual number of individuals is less. Nurses from the various districts serve in rotation as office nurse and the defectives are usually known to them by sight, thus frequently giving us a better history than the records at present can give, though it can be seen that the present record system will soon care for this adequately.

This system has met the approval of state and local authorities as covering the situation amply and satisfactorily. Admitting that it is not perfect, it certainly makes the yellow "Promise of Employment" card a

guarantee of a certain quality of employee and it protects the child from the dangers of its own ignorance and its physical disabilities. That we may attempt higher standards of examination in the future is possible, as in the case of the girls, and in routine re-examinations of a complete nature, but this must be as a result of a campaign of popular education and it is my personal belief that our present findings are fairly satisfactory.

In summarizing we must remember

that children between fourteen and sixteen are restricted by law to certain tasks which should be without danger to the physically normal person; that in New Bedford an attempt is made to build up the health and care for it from the first entrance to school; that each child that goes to work is given a thorough examination and passed for a particular type of work only; that each change of work means re-examination as extensively as indicated; that during the two years at

this time adequate watch of the child's health is kept through the continuation school health work under the same direction as in the general school system; and through cumulative records the general progress of the child is carefully watched.

Under these conditions I believe we are conserving the health of the working child and as I hope to show in a later paper, results seem to be gratifying as far as can be determined at present.

Selling Better Health to N. C. R. Employees

By F. G. BARR, M.D., COMPANY PHYSICIAN, NATIONAL CASH REGISTER COMPANY, DAYTON, O.

ABOUT thirty years ago, just after the National Cash Register Company had placed an improved type of cash register on the market, many were returned as defective. As the registers had been correctly designed, a careful investigation was made into the manufacturing processes; as a result production methods were perfected so as to make it practically impossible for a register to leave the factory with mechanical defects.

Soon after this, an official of the company, while passing through the factory at the noon hour, noticed a woman employee heating her coffee on a radiator. On making inquiry, he learned that the women were forced to eat cold lunches at their benches, there

being no place where they could get a hot meal. That this practice had a bad effect on their health was obvious, and steps were immediately taken to remedy the situation.

These two incidents marked the beginning of the health work among our employees. The company officials realized that they had been giving most of their attention to the product and not enough to the producer. Now the National Cash Register Company not only has three modern dining rooms for employees, as well as many other welfare features, but has also a trained medical force constantly endeavoring to "sell the employees" on the importance of personal hygiene and preventive medicine.

The report of the activities of our

medical department shows the extent of the work that is being carried on.

In 1922, 3,895 new applicants were examined and 104 rejected; 794 were examined for transfer; 15,409 received examinations, treatments, consultations and vaccinations; 3,199 visiting nurse calls were made, 26,648 other cases including injuries, minor injuries, surgical dressings, and x-rays were handled; 8,033 physiotherapy treatments were given, and the dental dispensary handled 9,303 applicants—a total for the year of 50,958 calls for service.

Our records show that the average number of hours lost per employee in 1922 on account of sickness, not including accidents, was 13.5 hours. Our sick list is checked each week by the foremen who send their reports to this department, giving the man's name, check number and amount of time lost on account of illness. We feel that is as accurate a method of checking sickness as is possible in a factory. This record, the best in our history, may perhaps be taken as evidence that selling health to employees is surely a worth-while proposition.

When it is considered that more time is lost by wage-earners through sickness than any other cause, it appears strange that it should be necessary to be continually educating either employer or employee on the value of health. Many employers still look upon health work merely as a welfare feature. But it goes a great deal further than that, for health has a direct bearing upon the quality of the product and the output of the factory. Then, too, the average employee is ignorant of personal hygiene and seldom realizes the value of disease prevention work to himself and family.

The selling of health must begin in the medical department, for so long

The employees of the National Cash Register Company receive a warm, well balanced noon meal. All food supplies are tested out in the company's research department.

Every employee has a physical rating. Those who are found to be under weight are supervised by the Medical Department. Free mid-morning lunches of malted milk are served every day to this group. Those who fail to gain under a corrected regime are re-examined and other measures undertaken for their relief.

as the doctors, nurses, dentists and clerks do not act as salesmen and saleswomen meager results must be expected.

The medical force at the National Cash Register Company at Dayton, consists of three doctors, one dentist, three nurses, two treatment room men, for physiotherapy, one masseuse, and three clerks. To insure success in the work among the employees we believe that every member of the staff should have the following qualifications:

(1) A vision of the value of preventive medicine.

(2) Adaptability. Patients ranging from the foundryman or trucker to the president of the company, must receive medical care which will lead them to have confidence in the medical department. The president and other executives must not feel that it is merely a department for the laborers; nor must the trucker or foundryman feel that the department is only interested in the executives and "white-collar men."

(3) Interest in the employees' troubles, no matter how trivial they may seem from the medical viewpoint. A curt, ill-considered answer to one of these trifling questions is often enough to make the employee a confirmed "knocker," as far as the medical department is concerned.

(4) The ability to sell health as a factor in production.

(5) Honesty. There is no place in

industry for the physician or nurse who merely asks the patient a few questions, looks at his tongue, fills in a report and sends him back to work. A doctor should be discharged upon the second offense of this kind, for thoroughness is one of the first essentials of success in industrial hygiene.

(6) The medical department employee must have his heart in the work.

The selling of health should begin before the applicant is placed on duty. In our factory, the first step is a thorough physical examination given by a doctor who is not looking merely for physical defects, but who is really interested in his patient. Here the doctor should give the patient such advice about his physical condition as may be of value to him. A dental examination should also be included.

Each of our new employees attends a health and safety lecture during the first hour of his employment. He then takes a trip through the factory. He learns the health and safety hazards not only in his own department, but in others. He sees the factory as a whole, and does not feel that his work is confined to one bench. This gives him a healthful mental attitude, one of the pre-requisites of a healthy body, and shows him that his new employer is interested in his welfare.

The employee is given a well-bal-

anced noon meal, and is assured of clean food. All food is tested in the company's Research Department.

Every cook, waiter, or other employee handling food is thoroughly examined every six months, to prevent spreading of disease. Drinking water, furnished from the company's own wells, is also tested for bacteria every day in the research department.

The new employee is invariably impressed with working conditions. Five-sixths of our walls are windows, insuring good light and ventilation. Our floors are kept clean by dustless sweeping, and exhaust systems are used on all machines with dust hazards.

When the employee applies for a transfer, he is asked to report to the medical department for another thorough physical examination, given as a protection to his health.

Every six months the employee is rated, and in this rating health is of first importance. The rating is done, usually, by a foreman and a supervisor, and the employee is rated A, B, C or D, depending upon his physical appearance, endurance, freedom from illness, and personal neatness. If he receives a rating of C or D the record is referred to the Medical Department, and the employee is called for re-examination.

The employee is further impressed with the importance of good health, when he sees scales brought into his department every six months. Every employee is measured and weighed. Should he be under weight, he goes to the medical department for consultation, and is given a malted milk card. Thereafter, until his weight increases

X-ray apparatus large enough to permit chest examinations as well as bone work is provided by the Medical Department. The x-ray work is also an important adjunct to the dental department.

to normal, he receives free malted milk every morning between nine and ten o'clock. If he loses, or if his weight remains the same, we discontinue this service. In 1921, 26,600 pounds of malted milk were distributed by the company in this way, as one means for bringing home to the worker the importance of his physical condition.

Results of this malted milk service show that within four months 79 per cent of the underweight employees gained, 2 per cent remained at the same weight, and 19 per cent lost. Those in the 19 per cent class were re-examined.

Sometimes it is necessary to sell the foreman on the value of health. This is accomplished largely by sending a comparative report each month to all departments, listing the number of treatments, given by the hygiene department, physiotherapy, dental dispensary and number of cases causing lost time and hours lost. This method stimulates the interest of the foreman who is not greatly concerned about the health of his employees, and at the same time encourages the foreman who does consider health of first importance.

Bulletins, pamphlets, and lectures are a part of the program of the selling of health—especially lectures. Information on health subjects given to groups of employees is one of the best means of disseminating health material.

A visiting nurse calls daily on our sick employees. She offers advice and suggestions, and gives whatever attention may be necessary.

About equipment: Every industrial medical department should have X-ray apparatus large enough to permit chest work as well as bone work. We find the X-ray is also important in the work of our dental department.

Another important part of our equipment is the laboratory. No medical department is complete without a laboratory where urine, sputum and blood may be analyzed.

In our physiotherapy department, or treatment room, employees receive treatments of various kinds, including fomentations, electric light cabinet baths, electrical treatments of various kinds, colon treatments and massages. These treatments are especially helpful in accident cases, where massage and the application of heat lessen the time of disability.

Many times when we are unable to sell an employee directly we succeed in selling him health through his

Physiotherapy is widely employed in medical service, the measure including fomentations, electric light cabinet baths, electrical treatment, and massage.

children. Our method of doing this is in connection with the children's meetings we hold in the N. R. C. school house. More than two thousand children receive health information along with entertainment and other educational features every Saturday morning. Many of these children, in later years will become employees of the company. They will come to us educated in the principles of personal hygiene, and fully alive to the importance of preserving health and preventing disease.

At a recent meeting we brought the scales into use and weighed each child. We also sent home with each child a letter to the parents and a card giving the actual weight of the child and the tables showing the proper weight for children of various ages. It was found that 42 per cent of the boys and 34 per cent of the girls were underweight; thus bearing out the oft-repeated statement that more than one-third of the school children in America are actually underweight.

Another thing that should not be overlooked is cooperation of the city physicians. Much good can be done through cooperation with them that would be impossible otherwise. The industrial physician should realize that he is practicing a specialty—industrial medicine. Consequently he should not assume to practice general medical work. He should always be anxious to refer cases to the employees' own physician, and then,

through his diagnosis and laboratory facilities, aid the physician.

Perhaps most vital to the success of an industrial medical department is a workable program which because of its practical advantages, induces the employee to look to it, voluntarily, for medical help, attention and advice. Our experience proves the efficiency of calls; the record of 50,958 calls with 13.5 hours lost per employee because of sickness seems to justify our belief.

Part-time Cooperative Courses in Vocational Education

Rehabilitation work throughout the country gives very wide application to the principles of organization of cooperative part-time courses as outlined in Bulletin No. 78 issued by the Federal Board for Vocational Education. It is based upon pioneer work in such coordination done in Ohio by Mr. C. F. Klinefelter, regional agent for industrial education for the Central States. It is held that this form of industrial education may be installed and maintained at very little expense to the community in cities as small as eight or ten thousand population, provided they have some one dominant industry.

Brooklyn has provided homes for 259,839 persons in the last three years at a cost of \$396,000,000. It leads the whole country in plans for new buildings filed in January, 1923.

Industrial Health Becomes Community Health

Health Service Keeps Pace With Industrial Expansion at Armco

By H. S. MURAT, M.D., CHIEF SURGEON, AMERICAN ROLLING MILL COMPANY, MIDDLETOWN, O.

A STORY of the first twenty years experience of the American Rolling Mill Company recounts a period of industrial history of great moment. They began operations in Middletown, Ohio, in 1901, at about the same time that the United States Steel Corporation came into existence and absorbed practically all of the rolling mill companies. Prior to that time sheet metal, billets, pig iron, and galvanized iron were products of distinct and separate industries. The American Rolling Mill Company was one of the first concerns to bring together all these branches of the metal business.

The amalgamation process, however, involved much more than developing a huge plant wherein could be controlled quality, quantity, and cost of manufactured steel. During the period when expenditures for plant expansion aggregated a total of nearly ten and one-half million dollars, and annual sales mounted from \$281,181 to \$13,262,835, the working personnel grew from seven hundred men to something more than forty-five hundred. Meanwhile, management, too, had undergone a metamorphosis. Labor saving devices, simplification of work, and conservation of human effort kept pace with increase of tonnage.

Such health and working conditions as now obtain in the mills were not achieved over night. In the early days "Safety First" was unknown. Difficult and dangerous work, then absolutely without protection for the men, is now fully safeguarded. The elimination of deep and dangerous ladle holes, changes from bottom-pouring to top-pouring, from manhandling to mechanical handling of ingots, from narrow gauge to standard gauge transportation, have been milestones in safety for the men and have speeded up production as well.

Needless to say, the newer methods built up a new personnel. Higher standards, both of working conditions and production, have gradually evolved the workman typical of the plant, loyal, adaptable, resourceful—a type impossible to develop under conditions which disregard the human element. In between the lines of "The

First Twenty Years," the industrial story of Armco, just issued, are dramatic pictures of spectacular difficulties of operation. Accidents, messes, lost heats, stresses, mark the steps of progress from the archaic methods of steel manufacture in the early days.

Medical Service Grams

It is the growth of the Armco Medical Service that concerns this article. During the period of construction of the East Side Works, and with the completion of this modern plant in 1911, the need was felt of providing better facilities for taking care of injured employees, a department fully organized to carry a service that did not begin and end with accidents, but which would include all that was sound in industrial medical practice and welfare work. The first step was the engaging of a surgeon to care for accident cases and to study the medical needs of the company. Two small dispensaries were established, one located in the rooms now occupied by the photographic department at Central Works, and the other in connection with the time office at the East Side Works.

These two dispensaries formed the nucleus from which has sprung the Armco main hospital, colored club hospital, Central Works dispensary,

shop dispensary, the treatment room in the administration building, and the physical examination department. Ambulance stations with motor ambulance service have replaced hand conveyed stretchers, and from the limitation of caring only for accident cases the work has been amplified to include the treatment of employees for injuries or ailments beyond those provided for under state compensation. This medical service is free of charge to employees.

The main hospital, built in 1911, is complete in every way. It contains waiting, dressing, sterilizing, and drug-dispensing rooms, as well as office, kitchen, dining room, and living rooms for the matron. An operating room, fully equipped, and wards for patients are provided. The laboratory makes available analyses of all kinds, both microscopical and chemical, and up-to-date x-ray apparatus is at hand for supplementary examinations.

The colored club hospital is maintained in connection with the Armco colored club. It has waiting, dressing, and drug rooms, with kitchen, pantry, bath, two private rooms and two ten-bed wards. This hospital is maintained for the care of colored men in the camp. Sickness as well as accident cases are cared for among the men.

The Central Work dispensary con-

Shops dispensary at East Side. The Shops dispensaries are suitably equipped and conveniently placed for routine care of the men on the job, as well as for emergent service when necessary.

The operating room, modern in plan and administration, safeguards the lives of the men in the mills.

sists of three rooms—waiting, dressing, and consultation. It is maintained for emergency care of men, sick or injured, at the central plant.

The shops dispensary at the East Side Works was built and equipped during the winter and spring of 1918. It is in close proximity to the forging and subsidiary departments and saves the time lost in transporting the men to the main hospital—an especially important feature in emergencies as well as in the minor routine care of the men. This dispensary is a little hospital in itself, having in addition to the usual rooms a rest room for girls working in the departments near by. Special provision for the care of office employees is maintained at the general administration building. It is further equipped with modern nose and throat treatment apparatus. Electric apparatus, light cabinets, and other appliances are there to care for the ailments common to office employees.

The personnel of the medical department consists of three full time physicians, six graduate female nurses, five experienced male nurses, three clerks, a matron, and two janitors. Service is rendered to all alike, regardless of race, color, nationality, or position. The scope of the work done by the department has gradually widened. No attempt was made at first to treat the minor ailments of employees. Today the medical department administers to the needs not only of the injured man, but any and all workmen feel free to visit any of

the various dispensaries for any injury or ailment, either real or imaginary, so long as he is on the job. When the condition of an employee becomes such that it is inadvisable for him to work, or he thinks he is not able to work, he is laid off and is advised to consult his family physician. The service is not extended to any other than the working members of the men's families. The value of the service is heightened by the personal contacts with the men. It is considered that personal acquaintance facilitates the work.

Recreational and working environment suitably safeguarded.

The physical examination department is primarily a safeguard to the health of the employees. Every applicant for employment is given a careful physical examination. This is of very great assistance in giving a

man the position for which he is best suited physically and mentally. Subsequent examination and treatment are given to men whose health requires it. Not infrequently defects and incipient disease conditions are detected and corrected before they become serious and cause loss of time to the patient. Signal service in this manner has been rendered in diseases of the heart, kidneys, and lungs, so often unsuspected or ignored by the average man.

Careful records are kept of all the work done by the department. In the case of accidents, the nurse or physician who attends the injured employee takes a complete history of the case, giving the man's name, check number, nationality, residence, whether married or single, length of service for the company, his experience on the job where he was injured; time, location and manner, nature and extent of injury; whether or not injury had been neglected, and all pertinent facts in regard to it. In the event of serious injury the safety engineer is notified at once for the purpose of securing all evidence possible as to the causation of the accident. If it appears that it might have been induced by defects of hearing, sight, or some other mental or physical factor, steps are immediately undertaken to correct the condition. In case of physical defect, transfer is effected so that recurrence of similar accidents will not be probable.

The clinical records of the employee show whether he is a frequent sufferer from headaches, dizziness, cough, constipation or other ailment.

Not infrequently such an employee is asked to report either to the physical examination department or to the hospital for a more careful study of his case. Any necessary laboratory investigation is done free of charge to

the employee, and any treatment given that is necessary to make the man more steady or efficient on the job. The outlay involved in this program is considered a good business investment to the company. Certainly the service has uncovered many incipient cases of heart, lung, liver, stomach, kidney, and bladder troubles, when well directed advice has been of the greatest benefit to the men.

This benefit is none the less positive because it is largely confined to preventive measures. Eight years ago it was not at all uncommon to encounter four or five cases of heat cramps, cases so severe that fellow workmen as well as doctors, and nurses would be called upon to assist in massaging the cramping muscles. The medical department has been instrumental in so modifying working conditions that severe heat cramps are now practically unknown in the plant.

Safety and Sanitation

Regular inspection trips through the plant are made by the physicians who are ever on the lookout for conditions which might be injurious to the man. The industrial causes of sickness and disease are often thus removed. Better support for rational health protection is secured from the men by this personal contact, which is supplemented by systematic educational talks.

Chemical and bacteriological examination of the drinking water supply

The desire of the company to serve its employees is probably the best seen in the sympathetic care of the children. Everywhere the human element is preserved.

is supplemented by activities which touch many phases of home life. Housing service is rendered; garden plats are provided as applied for; social service and visiting nursing service are utilized; dormitory provision and dining accommodations are made for the unmarried men; and a better mutual understanding is promoted by a monthly bulletin, of from forty to sixty pages.

An educational department is well manned to give technical and general training to those who desire it.

that every man shall come up for consideration at least once a year. Everywhere the men are handled as individuals. Systems and plans are subordinated to the development of the men. Decision, action, contentment, and general efficiency, therefore, characterize the working personnel.

The work of the American Jewish Joint Distribution Committee, which has provided relief in more than forty war-stricken countries during the last eight years, will be finished Jan. 1, 1925, it was announced recently. Plans for the completion of the work were approved at a meeting of the committee held in the home of its Chairman, Felix M. Warburg. The program includes a call for the immediate raising of \$1,200,000 by American Jews for the care of war orphans in Central and Western Europe. Only \$1,513,000 of the fund already raised remains to be allocated.

More than 1,000,000 persons receive free medical treatment in New York at dispensaries, and more than 7,000,000 persons a year are so treated at dispensaries throughout the country, according to the report of development of the United Hospital Fund.

The Central Safety Committee directs the personal service work.

is regularly made and hygienic conditions are everywhere maintained.

Nor is personal service work overlooked. A department for "Mutual Interest Work" was created in 1910. Safety work which is especially effi-

Recreational features are ample and varied. An insurance system has been in effect since 1917. The system of employment is so devised that promotion is made strictly on the basis of performance, and the routine provides

Computation of Partial Loss of Vision*

BY WILLIAM MEHL, M.D., BUFFALO, N. Y.

THE rating of impairments of vision has become an exceedingly popular pastime with the result that there is now a bewildering variety of reports and schemes for measuring and estimating such impairments. While six or seven years ago rating of visual losses was a fairly simple process today it has been made to appear a formidable problem complicated in the extreme.

The change seems to have begun when oculists were called upon to report and testify regarding permanent partial losses of vision. Among other questions, they were asked if the fact of a man's vision being reduced to 20/40, as the result of industrial accident, carried with it the implication that he had sustained 50 per cent loss of vision. There were those who adhered to the standard ophthalmological proposition that the fraction did represent 50 per cent loss of vision. Others took account of certain vocations wherein 20/40 did not necessarily mean 50 per cent loss of efficiency and replied in the negative.

The underlying principles involved in the rating of economic losses of vision are, when looked at as a purely common sense proposition, quite different from those applying to the rating of physical loss of vision. This fact seemed to have been overlooked.

Industrially considered, 20/40 may, in the average, mean less than 50 per cent depreciation of working vision. This, however, is of no direct concern to the oculist as such. The industrial loss implied by 20/40 (or any other formula for that matter), depends upon the point fixed by law as representing industrial blindness. We may admit even that, as a vocational asset, 20/40 does not, as a rule, mean 50 per cent depreciation of an eye. The physical loss of the first 50 per cent certainly is not as serious as reductions of vision beyond this point, considered as a wage-earning equipment.

When this view began to assert itself, then was the time for oculists, not being conversant with the peculiar demands made by various trades or industrial processes, to admit frankly that they were not qualified to pass on the question of industrial efficiency. Suggestions would have been in order

that a committee composed of employers, employees, carriers, legal advisers, and oculists would be best fitted to investigate the matter and arrive at a fair conclusion on a basis of average justice. Instead of taking this course, oculists and committees of oculists began to occupy themselves with the construction of tables which, they believed, would supply the need. The resultant confusion was aggravated when tables of this character were pushed to the fore as being authoritative, scientific and final. Indefensible as the procedure may seem, not a few oculists have persisted, contrary to the laws of the several states, in the use of arbitrary tables of their own selection when giving testimony in compensation cases.

The multiplication of free will offerings of such untenable tables was due largely to the failure to recognize or acknowledge that there can be no strictly ophthalmic formula for the rating of losses of vision, resulting from industrial accidents when economic considerations are injected. It further revealed a seeming disregard of the fact that physical and industrial losses are not always identical. Account should have been taken also of the experience that such a matter can only be settled finally by legislative enactment or equivalent authoritative rulings.

Chicago Report First Step

The report of the Chicago Ophthalmological Society in December, 1916 probably represents the first noteworthy effort to work out an acceptable basis for computing visual losses to be applied to compensation cases. In this report 20/40ths is accepted as 50 per cent of the vision of an eye. This conclusion is modified and minimized, however, by the introduction of four factors to be considered in connection with it: namely, (1) vision of injured eye, (2) vision of uninjured eye, (3) stereoscopic vision, (4) cosmetic result.

The next important contribution was the Milwaukee report. Then followed the report of the Medical Society of the state of New York, along with an explanatory appendix. Next appeared the report of the A. M. A. which was advocated as a national standard of rating, and yet only one year later we find this national standard is questioned by a minority of the same A. M. A. committee, and the ma-

jority itself finds it necessary to modify its own propositions regarding two or more essential points.

The regrettable lack of harmony on the part of ophthalmologists, as to what should be considered the standard for fixing the percentage of loss of vision sustained by a visual organ, as result of accidental injury, is traceable directly to the use of the various conflicting tables proposed for the rating of compensation cases. Oculists throughout the United States are inclined to subscribe to reports and tables advanced by their professional representatives in council assembled, although these propositions not infrequently run counter to the law in several states. For example, in the state of New York, loss of single binocular vision is legally equivalent to 100 per cent loss of one eye, while the tables most generally used assign to this function a varying value ranging from not more than 20 to 25 per cent. Moreover, officers having to do with the making of awards, have been advised that the proposed tables must be accepted as authoritative and that any contrary views must be dismissed as unscientific. Yet ordinary reasoning would suggest that the use of such tables is clearly contrary to law and therefore unjustifiable.

The State Industrial Commission of New York, recognizing the growing confusion, called a conference of eye specialists, at Albany, in October, 1920, to consider the question "What constitutes a fair estimate of loss of use of eye in workmen's compensation cases?" It was my privilege, at that time, to participate in the discussion, and believing that there was need of counteracting an evident tendency to minimize reductions of working vision, I centered my criticisms on this point. I attacked in particular those schemes which divided vision into assumed component parts, assigning to each of these parts a more or less arbitrary value. The suggestion had been given currency that central visual acuity represented not more than 40 per cent of vision, peripheral vision being allowed an equal rating, while only 20 per cent was accorded to loss of binocular vision. My discussion was chiefly an insistence that the central, peripheral, and binocular factors of vision, in their normal state, should not be used to minimize losses sustained by any one of the three factors. I argued

*Read before joint meeting of Industrial Hygiene Section of American Public Health Association and the Ohio Association of Industrial Physicians, Cleveland, Ohio, October 17, 1922.

that all factors, including color perception, were undoubtedly essential for perfect vision, but that they were not distinct and separable elements whose relative value could be determined ophthalmologically at the ratio of forty, forty and twenty, or whatever other ratio happened to be favored.

My contention is that vision should be interpreted as working vision, which is visual acuity, estimated after correction by lenses. Visual acuity undoubtedly is relatively the most important factor as regards industrial efficiency. Furthermore, it is the vision most frequently destroyed or reduced by accident. Accordingly, it would seem right that the highest degree of visual acuity obtained, after correction by lenses which the eye will tolerate as expressed in the Snellen figures, should determine the percentage of vision remaining.

If there should happen to be an extremely rare definite case of impaired peripheral vision, then would be the time to give special consideration to it.

Personally I should favor accepting the greater impairment of either visual acuity or peripheral vision as representing the total loss. For example, if the field of vision in one eye has been reduced 50 per cent and visual acuity in the same eye 20 per cent, I should be inclined to rate the loss for the eye at 50 per cent.

The theoretic suggestion that there is an unimpaired field of vision should not be advanced as an excuse for minimizing central visual acuity.

As a matter of fact traumatic impairments of peripheral vision by itself are so rare that it would be unjust to reduce the allowance for the ordinary eye injuries by suggesting that peripheral or binocular vision were not disturbed.

Visual acuity, or working vision, is determined universally by Snellen tests. Twenty to forty accordingly would represent 50 per cent loss of vision, fixing merely the degree of the purely physical loss sustained. When considered from the standpoint of industrial efficiency, there would be of course a different valuation placed on the fraction.

There are at least three principles by which permanent partial physical impairments may be rated: (1) The purely physical principle by which the medical examiner determines the degree of damage done, regardless of general or specific economic depreciations. (2) The specifically economic principle by which an injury is estimated according to reduction of earning ability which the individual has

suffered in consequence thereof in the pursuit of his chosen vocation. (3) The intermediary general industrial principle which fixes the monetary value of normally functioning members and organs of the body as a general industrial asset and rates the sustained physical impairment according to established schedules.

As we are dealing more particularly with the rating of permanent reductions of eyesight, and as the law of most states take no account of the actual economic losses the injured individual must face in consequence of the physical damage, we are concerned here only with the first and third principles. In other words, we have to do here, on the one hand, with the determination of the actual physical impairment, which must be established by the medical examiner, and, on the other hand, with the legal rating of such physical impairment, which is primarily the responsibility of the compensation referees. Unless we keep in mind these few simple practical facts, when we discuss particular phases of the law and their proper interpretation, we are sure to become entangled in irritating, wasteful, and fruitless controversies.

Ophthalmological Rating

No one can reasonably expect medical men to be conversant with the compensation law, the various changes it has undergone, the court decisions regarding it, nor even the principles upon which it is established. Our particular care is to examine and diagnose accidental injuries and whatever consequences may have resulted from these and then report our findings and opinions to the officers charged by the state with the making of awards under the compensation law.

If we could be permitted to adhere strictly to these lines—taking no account of the legal aspects of the determination of compensation cases—we should be able to confine ourselves to giving straightforward statements of purely scientific findings and then leave the legal interpretation of these findings to the officer or officers whose business is to know and administer the law.

The question of what percentage of sight an eye has lost as a result, direct or indirect, of an accidental injury is a case in point. All that the oculist, as such, ought to be expected to do, is to determine technically the degree of purely physical impairment sustained, using the peculiar means at his command, and then report.

Interpretation of the physical find-

ings of oculists is a problem apart. As regards degrees of impaired industrial vision, the rating must depend largely upon the point fixed by law as representing industrial blindness.

The question as to what shall constitute industrial blindness is one which cannot be determined by oculists, alone. Ophthalmology has no final word to offer on this subject. Industrial blindness, itself, is a rather vague term. If all vocational occupations could be considered separately, we might, in the course of time, be able to fix a point of blindness for each. Even this procedure would not result in supplying standards of unquestionable justice. Workers with us are not willing to be held to any particular occupation. They claim the right of freemen to turn to whatever work may appeal to them or in which their opportunities for advancement, economically or socially, are greatest.

There is then only one way for meeting the situation, and that is to make as careful as possible a survey of the various industries and other activities carried on in each state and on this basis to estimate the wage-earning opportunities of the workers employed and the visual efficiency required in the average.

Meanwhile common sense has acquiesced in the proposition that the legislature should fix the point of industrial blindness and to let experience dictate such legal modifications, or amendments of the law, as may be found to represent a closer approach to what is known as average justice. In the state of New York 80 per cent loss of vision is now the legal point of blindness. This is an achievement of considerable importance.

Following standard ophthalmological authorities, 80 per cent loss of vision is represented by the Snellen formula 20/100. I have not been able to find a single text book which does not adhere to this proposition. Such acknowledged authorities as Landolt, Noyes, William Campbell Posey, Juler, St. John Roosa, L. Webster Fox, and Hofrat Ernst Fuchs are all agreed on this point.

The question, accordingly, resolves itself to this: Does 20/100 meet the demand of average economic justice as representing industrial blindness? I am inclined to believe that it does, considering that the law covers trades requiring the highest degree of visual efficiency as well as unskilled occupations for which a minimum of vision suffices.

An open-minded, fair analysis of the proposition letting 20/100ths

stand as the point of industrial blindness is well worth while. To begin with, it means 20/100ths after correction with the strongest lenses the eye will tolerate, the courts have decided. Furthermore, we must bear in mind that a workman, afflicted with a loss reducing his vision to 20/100, is under the necessity and the attendant expense of periodical examination of his injured eye and the replacement of lenses, besides being under the disadvantage which a man wearing glasses is bound to experience in the labor market. The latter point is a rather serious one. Employers, other things being equal, prefer a man who has seemingly normal eyes to one whose defect in this respect is made prominent by the wearing of glasses.

Lenses Often a Barrier

Moreover, lenses are a positive barrier to admission in several trades. Many engineers and machinists find that oil and steam render their glasses opaque and disqualify them for the pursuit of their particular occupations. In addition to all other obvious depreciation of the visual efficiency and consequent wage-earning capacity, there remains the not at all unimportant fact that no allowance is made in any case of eye injury for any vision originally possessed by the injured worker in excess of 20/20ths. All things considered, therefore, the fixing of 20/100 as the point of industrial blindness may well be accepted as representing a fair approach to average justice.

The point of industrial blindness being fixed by legislative act, the remaining problem would be how to rate partial losses between this fixed point and normal vision.

Here again we are confronted by a confusion of estimates created by reports of committees of ophthalmological organizations. The objectionable feature of most of these reports is that standard ophthalmological principles are abandoned, in that an arbitrary rating is assigned to each ten foot loss of ability to see whether occurring between 20/20 and 20/30 or between 20/200 and 20/210. In other words, the proposition is advanced that the same amount of compensation be paid for the 10 foot loss between 20/20 and 20/30 as for the 10 foot loss occurring between 20/200 and 20/210. And yet we all know that the ten feet between 20/20 and 20/30 are of at least ten times greater value than the ten feet between 20/200 and 20/210. Applying geometric progression, the difference in values is at once apparent. For example, accepting the

point of blindness to have been fixed at 20/320, the fifty feet between 20/200 and 20/250 represent a loss of only 8 per cent, a loss equal in value to five feet between 20/20 and 20/25.

Moreover, it is easy to tell quite readily the difference between 20/20 and 20/30, as this represents a decided value. How can the difference be ascertained when vision is comparatively low, as between 20/100 and 20/110? Does it not seem unreasonable to assign to the undeterminable 10 feet between 20/100 and 20/110 the same value as to the clear distinction between 20/20 and 20/30? Here we are not on debatable ground but are confronted by an absolute scientific fact.

In Snellen tests we are dealing with visual angles and not with a straight line which may be divided into equal parts of ten foot each. Footage is not based on visual angles and will never fit in with them. Hence it is unwarrantable, from a scientific standpoint, to treat the difference between 20/20 and 20/30 as equal to the difference between 20/100 and 20/110, between 20/140 and 20/150, or 20/190 and 20/200, or any other ten feet distance. It is as absurd as if we should treat the circumferences of all concentric circles as of equal length, when they are equi-distant one from the other. The reason for the abandonment of ophthalmological rating in favor of footage progression was no doubt a subconscious prompting that ophthalmological impairment and economic depreciation of an eye do not always agree.

There is yet another objection to the tables presented as authoritative standards, and that is that each assumes a different arbitrary point of blindness. The question is essentially an industrial one, so far as workmen's compensation laws are concerned. Hence the fixing of the point of blindness for this particular department cannot be done by ophthalmologists alone. These could undoubtedly supply valuable suggestions, but the final fixation must be accomplished by legislative enactment which will have to prove acceptable to employers, employees, insurance carriers, and the general public as well.

It must be apparent to everyone that the point finally established as representing industrial blindness is an important consideration in the construction of any rating table. Such a table would represent chiefly a constructive effort to assign to each degree of impairment between normal vision and the fixed point of industrial blindness a definite valuation which

might then be given legal force by proper legislative enactment. In other words, the legislature would have to fix for every fraction of vision, as established by the Snellen test, a percentage of loss assumed to represent the impairment of the general economic usefulness of an eye. This percentage would then apply to all cases, regardless of the particular occupation of the injured individual, as is now being done in cases of amputation or ankylosis, of fingers, arms, legs, etc. In such a table account could be taken of the fact that the first one-half loss of physical vision is not as serious as the second half, economically speaking, and accordingly greater proportionate compensation be allowed for losses above 50 per cent than for those below 50 per cent.

With a view toward helping solve the problem, as it presents itself under the New York law, in a manner to preserve the principles of average justice from the standpoint of industrial efficiency, and allowing more for the second half of vision than for the first on economic grounds I suggested some time ago a rating table which would seem to meet the reasonable requirements of justice, common sense, and simplicity.

Rating Suggested

You will no doubt observe, when I present the suggested table, that it is based on "the footage fallacy." The excuse for it is that it does, in the particular case of New York, meet the industrial considerations quite satisfactorily. In the physical ratings from 20/20 to 20/100, footage and geometric progression are more or less far apart, but not anything like the divergence which would occur when the progression is carried up to 20/200 or to a still more remote point assumed to stand for industrial blindness. Besides, as a practical proposition, the industrially greater value of the second half of physical vision as compared with the first half is given due weight, and the footage scheme here seems to answer the purpose admirably, since it assigns a lesser value to the first part of vision. That is why I did not hesitate to adopt footage here.

The suggested table is, of course, constructed mechanically, with reference to the legal point of industrial blindness. The point of blindness having been fixed arbitrarily by legislative act, the table governed by it must necessarily partake of the character of arbitrariness. The fact that the table has found favor with fair-minded students of the problem would

seem to indicate that it meets the existing situation, and its legal adoption would end the prevailing unfortunate confusion. It is as follows:

	Loss	
20/25ths.....	61½	per cent
20/30ths.....	12½	per cent
20/35ths.....	18½	per cent
20/40ths.....	25	per cent
20/45ths.....	31½	per cent
20/50ths.....	37½	per cent
20/55ths.....	43½	per cent
20/60ths.....	50	per cent
20/65ths.....	56½	per cent
20/70ths.....	62½	per cent
20/75ths.....	68½	per cent
20/80ths.....	75	per cent
20/85th.....	81½	per cent
20/90ths.....	87½	per cent
20/95ths.....	93½	per cent
20/100ths.....	100	per cent

One more suggestion before I close. The former bewildering confusion created by various committees of oculists has of late become something like an approach to consensus of opinion on a few important matters. To begin with, there is no longer a putting off of the point of industrial blindness to an excessively intolerable distance. The tables based on assumptions which later study has proved unjustifiable have fallen with the change which has taken place. But what about the workers whose injuries

were rated by such tables? Would not the right thing be to urge the re-opening of cases which were compensated inadequately and give the injured workers their just due?

Awards under the compensation law must be based on findings of facts. These facts are modified, in certain instances, by arbitrary schedules governing the rating of permanent physical impairments. Legal enactment supersedes scientific opinion, whatever the latter may be, as regards loss of vision in an eye. A clear line of distinction must be observed between ratings which are to guide the administrators of the compensation law and ratings based on speculative assumptions.

Conclusions intended for the guidance of the legislature must not intrude as conclusions for the guidance of the state officers charged with the duty of making awards under the existing law.

By observing these practical limitations we shall soon overcome the prevailing confusion in rating permanent losses of vision.

Recent Compensation Decisions

BY DOROTHY KETCHAM, DIRECTOR, SOCIAL SERVICE DEPARTMENT, UNIVERSITY HOSPITAL, ANN ARBOR, MICH.

THE Supreme Court of Illinois, December 19, 1922, awarded compensation for death following empyema and pneumonia. A foreigner was working as a molder. He turned around to get a flask when some boards piled near on some sand, tipped and fell, striking him on the side. He was frightened and weakened, tried to get assistance in completing his molds, but being unable to do so, continued to work. The company claimed no notice was given and there was confusion about the nature and extent of injuries. The man's wife later went to the plant, told of the illness and how he was hurt. She was forced to talk through an interpreter since she could neither talk nor understand English. A midwife, at the request of the wife, attended the man, applying cold compresses and bandages as a neighborly act. Eventually the man became very much worse and, when a physician was called, a diagnosis of pneumonia and empyema was made. The man was taken to the hospital and operated. The physician testified that "there is a condition known as traumatic pleural pneumonia, that empyema is not necessarily the result of a blow; the

doctor could not tell what caused the condition in this case, and got no history of an accident in connection with the case. He had no interpreter and it was very hard to get anything out of Palocz and his wife." The cause of the empyema can only be determined from the history of the case. In this case, from the history, it is a reasonable inference that empyema resulted from the injury according to the Court and the award of the Commission was upheld.—*National Malleable Castings Co. v. Industrial Commission* 137 N. E., 520.

AN EMPLOYEE was crushed between a car and a prop in a coal mine and suffered several fractures and bruises to his back, ribs, and chest. He was taken to a hospital and later removed to his home. Pneumonia developed and, later, he died. The attending physicians testified that the injuries received were not serious and would not in themselves have produced death. The injuries, in their opinion, however, weakened his disease-resisting powers and in that respect contributed to his death. The Supreme Court of Illinois upheld the Commission, December 19, 1922. "It

is not uncommon for pneumonia to develop in a person who has suffered a serious injury to the thorax, and when a healthy man, crushed as Buckner was crushed, develops pneumonia while confined to his bed by reason of his injuries, and dies before his injuries heal, it is natural and reasonable to conclude that his death is the result of such injuries."—*Lumaghi Coal Company v. Industrial Commission*, 137 N. E. 439.

PNEUMONIA immediately followed the injury of a miner in the following case before the Supreme Court of Utah, November 24, 1922. The employee, while lowering a stopping machine weighing about sixty-five pounds, became entangled in the rope and was jerked a distance of six or eight feet and injured. Immediately he became ill, was taken to the surface of the mine, was for an hour or two in the engine room, and then taken home, when a physician was summoned who made the diagnosis of "the beginning of pneumonia." The condition became progressively worse despite the care he received and he died a few days later of "lobar pneumonia."

The evidence showed that prior to the accident the man was healthy, thereafter he became sick and died "without anything more or unusual happening to induce or cause him to have pneumonia." The Court states, "It is our opinion that it was not necessary for the Commission to find from the evidence that an injury resulting from accident was the sole cause of death. If the injury received in the accident materially contributed to the virulence of a disease he already had, and from which he died, that in our judgment, justified the award. From the evidence disclosed by the record here no just inference can be drawn but that an injury from accident either was the sole cause of lobar pneumonia or that it so accelerated that disease that ultimately death ensued. Upon either theory claimants were legally entitled to an award."—*Milford Copper Company v. Industrial Commission*, 210 Pac. 993.

The National Physical Directors Society announces that a general commission to study association physical work is in process of creation. A full-day session of the next Employed Officer's Conference, to be held at Blue Ridge, N. C., on May 27-30, 1923, will be given over to the commission for its report.

A Psychrometric Chamber and Its Uses*

BY R. R. SAYERS, CHIEF SURGEON, U. S. BUREAU OF MINES; SURGEON, U. S. PUBLIC HEALTH SERVICE, AND W. J. MCCONNELL, P. A., SURGEON (R.) U. S. PUBLIC HEALTH SERVICE, PITTSBURGH, PA.

THE invention of an instrument of precision for determining relative comfort in varying atmospheric conditions has been the aim of many investigators. Their endeavors have in part developed the different types of thermometers.

The so-called wet bulb thermometer has been perhaps the instrument of choice, but the Kata-thermometer is now being widely used. The Kata-thermometer measures its own rate of cooling, and its readings depend upon the changes in temperature, humidity, and air velocity, factors that likewise affect the heat loss from the human body.

That this instrument serves as an index of bodily comfort is generally accepted. It is very questionable, however, whether any single instrument can be designed that will answer this purpose.

The factors which influence heat production and heat loss are many and varied. We know in general, for example, that the heat regulation mechanism in man must, in order to maintain constant his internal temperature, produce a total quantity of heat above that amount required to carry on the indispensable physiological functions of the body, for the purpose of performing muscular work. Atmospheric conditions may alter the amount. If the atmospheric temperature is maintained at the body temperature, man's thermogenesis then diminishes. The factor of coordination of the nervous mechanism over the muscles of the body in response to sensations of heat and cold is difficult to evaluate, but is a very important one. Many other factors influence heat production and heat loss in man, and it is only by a study of the relative importance and correct correlation of these factors that we can hope to mitigate the abnormal physiological effects.

The advisability of making observations upon men subjected to accurately controlled air conditions is evident. The U. S. Public Health Service and the U. S. Bureau of Mines cooperating with the American Society of Heating and Ventilating Engineers have undertaken to do this, and a psychrometric chamber has been constructed at the Pittsburgh Experi-

mental Station of the Bureau of Mines.

This chamber consists of two adjoining rooms each $17\frac{1}{2} \times 8\frac{1}{2} \times 10'$, completely insulated from each other and the outside by walls composed of four inches of cork covered on both sides with cement. The ceiling and floor are also built of the same material.

Entrance is made from a small anteroom into the outer room through a refrigerator door also insulated with four inches of cork, and into the inner room through another refrigerator door of the same type. Figure No. 1 illustrates the plan of the chamber and accessory rooms.

The air conditioning apparatus, located in a space just outside of the chamber, consists of an automatically controlled distributing system, refrigeration equipment, humidifiers, heaters and fans. With this equipment it is possible to maintain any dry bulb temperature ranging from 20 degrees to 120 degrees F., and any relative humidity from 10 per cent to 100 per cent. Experiments can be carried on in either still air or in air with any desired velocity up to 1,000 feet per minute. Figure No. 2 shows the apparatus which maintains the atmospheric conditions.

When it is desired to procure a given dry bulb temperature and humidity, the corresponding dew-point temperature (the dew-point is the temperature at which moisture begins to be condensed from the air) is determined from the psychrometric chart, and the outside air is saturated

at this dew-point temperature by being drawn through the humidifier. The air entering the humidifier comes in contact with two banks of spray nozzles.

If the air to be conditioned has a dew-point temperature lower than required for a desired experiment, the water in the spray nozzles of the humidifier must be heated. This is accomplished by a thermostat in the dew-point chamber which, when set for the dew-point desired, operates by compressed air a diaphragm valve, thereby admitting steam to an ejector water heater at the inlet side of the water circulating pump. The thermostat opens and closes the steam valve, thus controlling the temperature within one degree.

If the air to be conditioned has a dew-point higher than required for the experiment, the water in the spray nozzles must be cooled. The water is circulated and cooled in a tank in which a direct expansion ammonia coil is placed. The dew-point thermostat controls a three-way valve taking cold water from the cooling tank and warm water from the humidifier, thus giving a mixture of the correct temperature for the desired dew-point.

The saturated air leaving the humidifier is drawn through a conoidal fan and blown over *vento* steam heaters. A diaphragm valve on the heaters is controlled by a thermostat and makes an automatic control of the dry bulb temperature. The conditioned air is blown into each room through a plenum chamber with a large number

Fig. 1.—Layout of psychrometric chamber constructed at Pittsburgh Experimental Station of the Bureau of Mines.

*Published by permission of Director of U. S. Bureau of Mines, Department of the Interior.

Fig. 2.—The apparatus for the control of temperature makes it possible to maintain any dry bulb temperature ranging from 20° to 120° F. The air observed may be still or moving with any desired velocity up to one thousand feet per minute.

Fig. 3. Figures in the test chamber. When it is desired to procure a given dry bulb temperature and humidity, the corresponding dew-point temperature is determined from the psychrometric chart. Separate controlling systems are provided in the two chambers.

of outlets in the side for even distribution. A hand-controlled direct expansion ammonia coil is installed in each room so that the dry bulb temperature may be made lower when desired. A return system connects each room with the intake of the humidifier so that the air may be recirculated if desired.

In order that different conditions may be maintained in each of the two rooms, as is frequently desired, each room is equipped with special apparatus.

A direct heating system has been installed in the inner room. After the conditioned air enters this room, its dry bulb temperature may be lowered by the ammonia coils, or raised by the heaters. The dew-point, however, will remain unchanged as long

as the dry bulb temperature is not lowered below the dew-point temperature and cause condensation. In the outer room a bank of spray nozzles are placed in the plenum chamber and operated by compressed air. In this room the entering conditioned air may have its dry bulb temperature lowered by the direct expansion ammonia coil or it may have its dew-point raised by liberating water into the room through the spray nozzles in the plenum chamber. A gyrostat operates the additional spray nozzles automatically. The ammonia coils are part of the refrigeration equipment which consists of an ammonia compressor, condensers, accumulator, separator, motor and expansion coils. An air compressor with storage tank supplies air for the automatic control.

From this description it is apparent that any desired atmospheric condition may be obtained. The individual rooms are adequate in dimensions to accommodate a sufficient number of subjects for observation. Wherever possible the instruments for measuring physiological reactions are located in a room adjoining the test chamber.

Experiments with the Kata-thermometer have established definite laws of losing heat from a dry and wet surface. With the elaborate equipment of the chamber human subjects can be used instead of the Kata.

The sensitiveness of the body to changes of temperature and humidity is ascertained by having subjects pass from one room of a given temperature and humidity to the other maintained at a slightly different condition.

The physiological effects produced by different atmospheric conditions

are observed on human subjects during their stay in the chamber. This work may well be divided into four phases as follows:

- (1) Observations on subjects at rest and in still air.
- (2) Observations on subjects at rest and in air of different velocities.
- (3) Observations on subjects at work (either physical or mental) and in still air.
- (4) Observations on subjects at work and in air of different velocities.

The subjects who are subjected to the tests first rest for two hours in a room where the atmospheric conditions maintained are similar to those of any well-ventilated rest room. During this period the pulse and respira-

Fig. 4.—Body temperature is taken by means of electro-thermocouples and potentiometer. This picture shows the reading of the potentiometer.

Fig. 5.—Pulse Tracing.

Fig. 6.—Respiratory tracing by means of Kymographion.

tory rate, body and surface temperatures, and blood pressure are recorded. At the end of the two hour period the subjects are weighed. On entering the test chamber they insert the rectal "thermocouples" and strap the tubing, for recording respirations, around the chest. Figure 3 shows the subjects in a corner of the chamber in a test. During the high temperature work the subjects strip to the waist, thus approximating the conditions of men working in high temperatures in the industries.

In these experiments the blood pressure is measured by means of a mercury sphygmomanometer, the auscultatory method with the subject in a sitting position being used. The oral temperature of each subject is taken by the "one-minute" clinical thermom-

eter. These thermometers are kept in ice water during the high temperature experiments. The rectal and surface temperatures are recorded by means of thermocouples, which are connected to a potentiometer in an adjacent chamber, as shown by Figure No. 4.

A permanent record is made of the pulse on smoked paper whenever desired, as illustrated in Figure No. 5.

Respirations are recorded at intervals unknown to the subjects by means of the kymographion (Figure No. 6). An inflated tube is strapped around the chest, and connected by means of long rubber tubing to the kymographion.

Many difficulties are encountered in determining the basal metabolic rate, as it involves transporting the expired breath of the subject undergoing the test to the apparatus in an adjacent room. The subject breathes through the mouthpiece of a Gibbs oxygen breathing apparatus, which is connected to a graduated gasometer (Figure No. 7). The mouthpiece referred to consists of two butterfly valves, one of which opens when the subject inhales and closes when he exhales, while the other closes when the subject inhales and opens when he exhales, thus conveying the exhaled air to the gasometer. A small nose clip prevents nasal breathing during the collection of the sample. Three samples of thirty liters each are collected from each subject at one-hour intervals during the test. From each of these an average is analyzed for CO₂ and O₂ on a Haldane apparatus. Analyses of the blood for haemoglobin and sugar, of the sweat for acidity and

chloride concentration, and of the urine for albumen and sugar, have been made at intervals.

The temperature and humidity of the air in the test chamber are determined by means of an automatic indicating psychrometer. Analysis of the air in the chamber also is made at intervals during the tests.

After leaving the chamber the subjects are again weighed and a record is kept of the afterfall in temperature and pulse, and notation is made of any unusual symptoms following the exposure.

New Utility Stand and Sterilizer

Hospital executives are realizing more and more the economy of having electric sterilizers in clinics, dressing rooms, and wards. They take the place of the old gas plate, and because of their automatic cut-offs soon pay for themselves in the goods and instruments which are saved from being burned up. The new cut-offs are really dependable now.

An electric sterilizer of course has to be put on some sort of table. One

manufacturer, realizing the difficulties of the situation, has just put out a convenient stand which holds either a 13 inch or 16 inch sterilizer at one side.

The table top is vitrolite, guarded by nickel rails. A removable tray for instruments swings from a bracket underneath and a good sized cabinet provides for the storage of linen or other supplies. The table is as complete as can be desired.

Fig. 7.—Instrument for sampling and analyzing the breath.

Inspection Standards Vary

STANDARDS of factory hygiene vary, but not more than do the qualifications of factory inspectors. In connection with studies of problems connected with workmen's compensation, the National Industrial Conference Board has made a recent inquiry which brings out the remarkably wide variation that exists in the practices and regulations of the several states in the selection of these officials.

In nine of the states—California, Illinois, Maryland, Massachusetts, Minnesota, New Jersey, New York, Ohio, and Wisconsin—candidates for appointment as factory inspectors must pass civil service examinations. In California the safety engineers and inspectors on the staff of the Industrial Accident Commission must be specially qualified either through technical training or practical experience for their particular branch, the work being divided under a superintendent of safety, into mining boiler, mechanical, electrical, construction, shipbuilding and elevator divisions.

References are also required, and every man's history is carefully checked, while the written examination is supplemented by an oral one in which experts in each specialty assist the examining board. In Illinois the examination is chiefly concerned with the applicant's knowledge of the laws to be enforced by the division of factory inspection. Besides the inspectors, two part-time physicians and some other technical men are also attached to the division's staff.

In Maryland, where the initial salary is from \$1,200 to \$1,500, the applicant for appointment as industrial inspector must be at least eighteen years of age and have a high school education or its equivalent, "preferably with additional sociological training, successful inspecting or investigating experience, familiarity with child and female labor regulation, ability to prepare concise reports, knowledge of the industrial safety and sanitation, ability to judge situations and persons accurately and quickly, keenness of perception, integrity, resourcefulness, perseverance, good address and tact." Special credit rating, equivalent to not less than 20 points on a basis of 100, is given to men or women, honorably discharged, who are veterans of the World War.

The examination in Massachusetts is very thorough, dealing almost wholly with problems of sanitation,

ventilation, experience in safeguarding machinery, accident prevention work, occupational diseases and similar industrial matters. Of the thirty-six inspectors in the State, six are women. Many are college graduates and all have had training in some industry.

Practical experience, coupled with ability to pass a competitive Civil Service examination, both written and oral, is required of all candidates for appointment as chief factory inspector, elevator inspector, railroad inspector, factory inspector in Minnesota.

Factory inspectors in New Jersey "are examined in elementary subjects such as arithmetic and also in their knowledge of methods of dust removal sanitation, machine guarding practices, building construction and fire prevention." They must also be familiar with the various laws enforced by the state department of labor. Compensation varies from \$1,440 to \$2,360 a year, and can be increased at any time in the direction of the Civil Service Commission. Practical mechanical experience and a thorough knowledge of conditions existing in industrial plants are required to pass the civil service examination in New York State, and many of the inspectors have special technical qualifications also.

Factory inspectors in Ohio are examined for a knowledge of general safety practices for workshop and factories, but "the men usually appointed are not specially qualified nor are they technical men." In Wisconsin, the written examination is followed by an oral interview before examiners of the Civil Service Commission and representatives of the State Industrial Commission to determine their personal qualifications.

"Most of our factory inspectors," says the New York Member of the Conference Board, "are practical shop men who are experts along some one particular branch of industry, but where problems come up that they cannot handle the matter is referred to one of our engineers." "We have conferences of all our field men once in two months, in which we spend a day or two in discussing all problems. The various field men bring up questions that have originated in their districts and these are discussed. Another object of these conferences is so that we may have uniform enforcement of the commission's requirements."

In other states to which letters were addressed, no written examinations are required. Connecticut inspectors are appointed by the Commissioner, and are selected according to his estimate of their fitness for the work required. Of the nine deputies in this State, the law requires that two shall be women. The Michigan law makes no specification of qualifications required, although it is the policy of the department to get the best men possible for the work.

In the Pennsylvania Bureau of Inspection, which is under the supervision of the Commissioner of Labor and Industry, provision is made for fifty-eight inspectors, divided into four grades. The four members of the fourth and highest grade are a licensed physician, who is chief medical inspector; a mechanical engineer, expert in ventilation and accident prevention; a chemical engineer, and a civil engineer; and an expert in fire prevention and building construction. The two medical inspectors of the third grade, one of whom shall always be a woman, are both licensed physicians. The two inspectors of the second grade act as supervisors, with offices at Pittsburgh and Philadelphia, and direct the work of the fifty inspectors of the first grade, of whom at least five are always women.

Practical experience for at least ten years is required of every appointee as deputy or assistant deputy inspector in Indiana. The deputies, of whom there are three, hold office for four years, with an annual salary of \$2,000. They divide the field, one being inspector of buildings, factories and workshops, one of boilers, and one of mines and mining. Each deputy may appoint five assistant inspectors at a salary of one thousand dollars a year.

The two inspectors in New Hampshire are appointed by the State Labor Commissioner. The present incumbents, says the Commissioner, are "good practical men," with wide general knowledge of the kinds of machinery used in the State, and with "ability to meet other people's point of view on subjects of safeguarding machinery and also sanitary and hygienic conditions of workshops and plants they visit."

In Rhode Island, where the chief inspector is assisted by a deputy chief and three assistant inspectors (one of whom is a woman), the board's inquiry was answered by a single brief sentence: "We would say that the only qualification required is common sense."

INSTITUTIONAL HEALTH

The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents

Convalescent Care in Suburban Communities*

By FREDERIC BRUSH, M.D., MEDICAL DIRECTOR, THE BURKE FOUNDATION, WHITE PLAINS, N. Y.

THE reproach of medical and public health practice today is in the neglect and faulty care of convalescents, chronics, the handicapped, and the various borderline nervous and mental ailments. This zone of ill health is unpopular with the physician and poor instruction on this subject is given in the medical schools. Social service, reconstruction, and vocational and employment agencies for the handicapped indicate increasing auxiliary efforts. But private and public health physicians generally will take right interest only when they are brought to realize that quacks and cults thrive mainly in this very field, which the former have for years partly surrendered, through indifference and inefficiency in follow-through treatment.

Convalescent care in practice covers in some degree this entire health zone. Now there is fortunately a revival in this branch, after more than a half century of lethargy. Its history, advancements, new standards, and literature may not here be reviewed. Those interested are referred to an authoritative series of articles by Dr. John Bryant, of Boston, now being published in the *Boston Medical and Surgical Journal*. The conclusion is that the convalescent home in the country is the best proved instrument for the restoration of these border-zone persons, who make up a surprisingly large percentage of populations everywhere.

A study of the present convalescent provision and needs of Westchester County, N. Y., will apply broadly to many other small city and suburban communities. This county, holding nearly four hundred thousand people, in part functions integrally with the

great metropolis, but grades through its small cities and towns into fairly rural conditions in the outlying sections. According to certain standards and ratios now becoming well accepted there should be for the county two hundred to three hundred convalescent beds available the year round. Instead there are practically no convalescent places definitely for county patients, and only a modest fractional provision is obtained through the courtesy-use of New York City homes located herein. The above apportionment of two hundred beds minimum takes fair account of the comparatively open-space and favorable living and recuperation conditions prevailing. Without detailing the studies and reasons, it may be conclusively stated that suburban and rural communities need less population-proportion of convalescent bed facilities than large cities, but that

this lower ratio need is at least equally valid and pressing.

Who in such communities want these convalescent beds?—Factory and all other classes of wage-workers whose homes are unsuitable for good recovery after illness or operation (the houses or the people in them may be the obstacle); many servants, even in large establishments; farm and grounds employees especially; people of usual ample means who have exhausted their resources in the struggle for health; those showing marked and progressive fatigue at the daily task, be it housekeeping, railroading, book-keeping, child-rearing, or other; the ageing and the handicapped, the discouraged and the constitutionally inferior, requiring bracing up before readjustment to more suitable occupations and modes of life; large numbers of nerve-worn and half-ill persons who are often surest of restora-

*New York City has about one-half of all convalescent beds in the United States, some of the Homes being in New Jersey, Connecticut and Massachusetts.

*Read before the New Rochelle Medical Society, New Rochelle, N. Y., January 8, 1923.

Dancing, indoors and out, proves highly restorative, especially as mental therapy.

tion by a decided change, and a temporary separation from their own people.

How does the modern convalescent institution function in bridging this recognized public-health dead-space? By giving time, peace and rest, and a new advanced reconstructive training and viewpoint, to its variously subnormal patients. These three vital elements to full recovery and re-entry to a higher grade of living are precisely what cannot be obtained by remaining longer in hospital, nor in the average household.

Community convalescence is economically and medically the soundest health measure awaiting general adoption—now that infectious disease prevention and social service are so well established. A few American cities are beginning to plan convalescent plants in their health and industrial programs, essentially along with hospitals, dispensaries, sanatoria, home visiting services, etc. All populous and fairly concentrated communities should so plan and provide, for their rating in public health will be more and more determined by their records in prevention, and in care of the subnormal borderliners.

The definite position of supervised country convalescence in the health-effort cycle may well be further indicated by examples: Great numbers of the shorter-term medical and surgical cases (exemplified by pneumonia, hernia and appendicitis) are given from one to four weeks of rest, grading into near normal activity, and sent back to full physical and social restoration; without such term many of these work too hard too soon and drift into relapse, semi-invalidism and low-grade living; they clog the dis-

pensaries and make incomes for the charlatans. Note that this very class is then best lifted back to normality by re-diagnosis plus a fairly long country re-construction plus right employment-placing and long follow-up; a result only attainable by having the convalescent home outlet. The country home relieves the hospital and the family and sooner and surer restores all forms of tuberculosis (excepting

litis and like protracted ailments. Furthermore, the term in the home is being much used as a testing of diagnosis and previous therapy, and of the patient's temperament and fitness for follow-up readjustments. The list of diagnoses for a year of six thousand admissions at the Burke Foundation includes about all the terms in medicine.

The above is the fairly understood and obvious convalescent classification; but quite equal in quality of result, and gaining in numbers with further experience, are the variously and atypically debilitated, nerve fatigued, anemic, under-nourished, depressed, disheartened and maladjusted folks who respond to a rest-cheer and re-training time in the country place so well that one in the work inevitably seeks more of them, as against other classes. It is too little recognized that plain overwork is a fact, and a medical and downward-progressive condition; convalescent homes only can give most of these the right treatment. It is just in this zone that the newer American types of homes are specializing and advancing into wider fields—in preventive and what we may call "hold-on" recuperations; and are promising to take no small part in our whole scheme of preventive medicine.

A croquet tournament with strong cottage rivalry. The grounds and equipment are made and kept in order by patients.

active pulmonary), heart disease, rheumatism and chorea (taken up to degrees of moderate crippling), many border nerve and mental states, thyroid disorders, orthopedics, empyema, lung abscess, nephrectomy, osteomye-

Westchester has within its borders more convalescent beds than any other county in the United States—about fifteen hundred (not all the year round); but with a few exceptions they are not for county patients. Be-

cause New York's six millions of people to find our area the best place for rest and recreation it should not be thought that the county inhabitants are in a uniformly highly elated and vacational condition, or that they do not need certain definite convalescent facilities to maintain a creditable state of the public health. How may this section, which will soon be holding a half-million people, work toward an adequate provision in this line? In three ways—(1) by getting *en masse* to more of the resident institutions, (2) by development of a convalescent branch to Grasslands, the County Hospital, and (3) through the eventual establishment of one or more private-corporate smaller specialized homes distinctively for county patients.

In 1915 the Burke Foundation, maintaining three hundred convalescent beds primarily for New York patients, offered use of a fair proportion to this county. The county has since agreeably availed itself of the opening, to the extent of twelve or fifteen beds average occupancy, and a total of thousands of patients. The county health workers in certain sections cooperate fairly well, while others rarely apply. This indicates how much convalescence is yet a matter of health education; and also that the county possesses in the Foundation a great restorative agency which

Men, convalescent from various ailments, in the occupational therapy shop.

but considering its broader phases, such as the homes' freedom from taxation, etc., it would seem that the county health authorities should press for a reasonable local use of many of these New York institutions, with a frank and valued reciprocation of service in ways that have already proved feasible.

To the able and ever progressive management of our large County Hospital a distinct provision for convalescents and other half-ill non-contagious patients has already forcibly appealed; they constantly make some

favorable opportunity to pioneer in county convalescence. Quicker and better restoration, the care of more patients and the tax-savings are arguments enough.

Women of means and high social betterment motives have been the leaders everywhere in founding small rest homes. There is every reason why this already crowding and semi-metropolitan community should have three or four of these for its own people. Health officers, physicians and lawyers are best able because of contacts, to divert thought and funds to this desirable purpose. Beginnings may be modest and comparatively inexpensive; full details for inception and procedure are available.

In conclusion: Future medical practice and public health routine must correct what Bryantwell calls the "clinical neglect of convalescents" and the borderlines of chronicity and invalidism. But any decided advance depends first upon the establishment of adequate country recuperational institutions, run on skilled specialized lines, and at low cost. Westchester County, the largest typical American suburban and part-rural community and approaching a half-million population, is full of convalescent homes, yet has scarcely none for its own people and is illy using what it has. No other advance at this time would more improve the community health, morale and general efficiency, with a large saving to workers, benevolent donors and to taxpayers.

Women's ball-throwing contest in a convalescent field day. Prizes were awarded.

it has so far failed to fully appreciate and utilize.

Some other smaller metropolitan homes located in our area are increasingly welcoming a few local cases; this question is complicated;

attempt to segregate this group within their hospital. A removed convalescent branch, of much cheaper construction and daily maintenance cost, is however recognized by them as the best solution. Here is a most

The National Health Library

Some five or six years ago four national health organizations, then in varying stages of development, each began to consider the value of adding a trained librarian to their respective staffs; the primary purpose of such library service in each instance being the immediate use of the office staffs. These four organizations—the American Social Hygiene Association, the National Committee for Mental Hygiene, the National Organization for Public Health Nursing, and the National Tuberculosis Association realized that a new literature was in the making in each of their respective fields and that an important function of the director of the health library would be to help to produce the literature of which there was such a crying need.

The cooperative adventure in librarianship that resulted is described by Florence Bradley, extension librarian of the National Health Library, in the *Library Journal* of February 1, 1923. Affiliation, she says, with public libraries was to save them the necessity of making the same unique collection of materials as that brought together by the social hygiene group, for instance. The beginning of the National Health Library was marked by the unification of the four societies named with the groups represented in the National Health Council. Through a common service committee, experts of the several groups were brought to function as specialists in the literature of their special fields, so that now a working arrangement is affected whereby public health literature as a whole is served by a staff consisting of three trained librarians, a library assistant, a stenographer, a typist, a clerk, a page, and on special occasions a cataloger.

The most unique thing about the budget so far is that 70 per cent of the income is expended for salaries, and nothing for books. Twelve per cent covers rent, and 18 per cent running expenses. While many of the most important additions to the library shelves are in pamphlet form, books are needed. The 648 volumes added last year were selected with great discrimination, and were contributed. Reference work is very specific and thoroughly practical. Bibliographies are prepared, and reading lists are sent out each month according to needs indicated by library correspondence.

To meet the urgent need growing out of the increasing emphasis on health education an extension service

has been developed. So far this has taken the general direction of (1) starting reference collections of health material, both pamphlets and books; (2) making health literature available through traveling libraries or extension divisions, this notably in Pennsylvania; (3) interpreting to small libraries, especially rural libraries, the books of fundamental importance which should be considered in relation to annual book budgets, notably in Oregon. The most unique service is rendered in the newer administrative projects about which no literature exists.

Two groups are served: the trained public health worker and the interested layman, this latter group including the school teacher in search of health primers, the mother wanting material on child care, or the club woman trying to inform herself on sex education. For the public is becoming community-minded, and the needed service that interprets health information that is fundamentally scientific and unquestionably authoritative and that will lead to inspiration and achievement in public health activities is an altruistic as well as an educational enterprise.

Where Physical Training Overcomes Fear

Albert R. Dupont Photo.

The handicap of the blind is not so much physical as psychic, for the retardation of the blind is due to their necessity of evolving new means of communication, and finding self-expression in spite of the inhibiting influences of their unexplored, and more or less to be dreaded environment.

THE education of the handicapped, whether the inhibiting defect be the loss of a sense—as of sight or hearing—or the maiming of a limb, resolves itself into getting the patient to accept the situation, to cease to regard himself as “different,” and to become social in his instincts and expression.

It was a great boon to the blind when they were enabled to read through educating their sense of touch to detect the word signs of the Braille system of printing. The means of educating the blind were further extended through phonographic methods. But the chief service of education is to enable people to live to-

gether in mutual sympathy and understanding and it may thus well be regarded as an even greater achievement so to attune these handicapped children through a sense of rhythm that they become capable of cooperative activities and of social response.

Miss Alma Guy, director of recreation, of the New York Lighthouse for the Blind, has for the past six years conducted her work so effectively that the blind are enabled to interpret their thought by action. The girls have learned to play. In the illustration given three girls totally blind and one partially blind are seen in a figure of an intricate rhythmic dance.

The Dispensary and the Out-Patient Department

Describing Organization of Welfare Work by the New York City Hospital

By CHARLES B. BACON, M.D., MEDICAL SUPERINTENDENT, THE NEW YORK CITY HOSPITAL, NEW YORK CITY.

THE historical incident associated with the development of every activity is marked by a period of beginning, progress, achievement, and finally its maintenance and operation; specifically, the performance of its particular function. Each period requires earnest thought, wise judgment, cooperation and interest between individuals and groups of individuals. It is of extreme importance that the personnel be composed of men and women disposed and competent to judge between an actual need and a fad or something that is popular yet not carefully conceived, and for which no actual imperative need exists. The City Hospital Dispensary and Out-Patient Department is a concrete example of a carefully considered and actual need extending over a period of many years.

Our Beginning

I well recall the discussions and events that took place years ago regarding the need and development of this dispensary, the different ideas expressed, and finally the elimination of many of these ideas. Out of these deliberations evolved a definite policy and fixed program. Our problem was made somewhat more complex by reason of the fact that the City Hospital, the parent institution, is located on Welfare Island, while our object was to establish, maintain, and operate a dispensary on Manhattan Island. The question of transportation and operation of this activity, thus removed, yet each service of necessity directly articulated with the corresponding service and departments at the hospital, caused us to delay action until access to and from the hospitals located on Welfare Island to Manhattan and Long Island could be effected by way of elevator service to the Queensboro Bridge. This having been accomplished, no time was lost in carrying out our dispensary program.

No municipality known to me possesses a more ideal hospital location than the City of New York on Welfare Island, where two of our largest general hospitals are located, also a special hospital for neurological and infirmity patients, and the New York

City Home for the Aged and Infirm (Manhattan Division). Furthermore, the dispensary has an ideal location from this point of convenience and accessibility to the hospital, also from the viewpoint of community service. The administrative and professional staffs and co-workers build the foundation and add something to its construction during each succeeding administration. Thus the work of successive commissioners is cumulative and, the ultimate objectives for which we have striven are finally attained.

The need for this new activity was brought to the attention of the Honorable Bird S. Coler, commissioner of the Department of Public Welfare, during the early part of his administration; by reason of his interest, cooperation, and initiative, its achievement and establishments in connection with the New York City Hospital were made possible. This activity marks a new and notable epoch in the history of the New York City Hospital—a history now extending over a period of approximately one hundred years, and made possible by the foresight and wisdom of men and

women, professional and lay, who during those early years realized that increased facilities, improved methods, and humane treatment were the right of the dependent sick and injured in New York City. To be convinced of this fact one need only scan the early history of the old Bellevue Hospital.

Marked Progress Made

On August 1, 1920, the elevator service from Welfare Island to the Queensboro Bridge was placed in operation, thereby making City Hospital directly accessible to Manhattan and Long Island. This elevator service is in conjunction with the new Island Storehouse and is, in fact, an integral part of it. Three electric freight elevators equipped to handle ambulances, fire equipment, and apparatus, trucks, automobiles, etc., are in constant operation, together with two passenger elevators. This service furnishes ideal transportation to and from the hospital, and makes the dispensary and hospital directly accessible—the distance being covered in approximately five minutes.

Inasmuch as the Queensboro Bridge

Section of the general waiting rooms, together with offices of the registrar and social service nurse.

A portion of the medical clinic rooms. Each clinic room is immediately accessible to the respective service clinic waiting rooms.

starts from Fifty-ninth Street and Second Avenue, a dispensary located in this vicinity at once became the place of choice. Fortunately, the city already owned property consisting of a four-story and basement brick building at 220 East Fifty-ninth Street, between Second and Third Avenues, less than a block from the entrance to the Bridge. From the point of accessibility, this location is most favorable. The Fifty-ninth Street surface cars, running east and west, pass the main entrance to the dispensary. One-half block to the west is the Third Avenue Elevated Railroad, and Fifty-ninth Street Station, also the Third Avenue surface car lines running north and south. One block farther west is the Lexington Avenue surface lines, running north and south, also station to the Interboro and Brooklyn Rapid Transit subways. To the east, the Second Avenue Elevated Railroad, with station at Fifty-seventh Street; also the Second Avenue surface lines running north and south.

The building has been extensively remodeled in accordance with a carefully prepared detail and plan, with the result that it now affords a physical plant ideally adapted for a dispensary and out-patient unit. Modern conveniences are afforded for each dispensary service. A well planned and equipped registrar's office, social service and follow-up department, pharmacy, and laboratory, with quarters for a lay staff to care for the building,

and a professional staff to receive emergency calls at all times, are provided. The several clinic rooms are separated from one another by wood and ground glass panel partitions. Ample waiting rooms afford separation for men and women. The rooms are well heated, lighted, and ventilated, and provided with running water. All floor surfaces are covered with linoleum. The equipment throughout is

new; carefully selected, specified, and purchased. Electric sterilizers have been installed in all the surgical and operative clinics. The visitor is at once impressed with the completeness and orderly arrangement of the building, its equipment, and the well-trained, efficient staff of workers.

A carefully planned medical record room has been installed, and all the record forms of each department adhere to a definite color scheme, the records of each distinctive from those of other departments. There are ten professional services, each in charge of a director of service, with a chief of clinic, responsible to the director of service, who visits the dispensary on his regular clinic days. The chief of clinic is entitled to as many assistants as may be necessary to properly care for the work. Furthermore, the chief of clinic is nominated to the Medical Board by the respective divisions on which he serves, and the position carries with it that of "Assistant Attending" to the same service at City Hospital.

The hospital is supplied with a complete dispensary record of each transfer; also the dispensary of each patient discharged from the hospital and referred to the dispensary. Furthermore, each discharged patient referred to the dispensary is presented with a reference card.

A brief description of the general plan, floor by floor, is here given.

Basement.—North (front) is located the drug store—well lighted,

Section of the eye, ear, nose, and throat clinic. In connection and in direct communication with this clinic is a well equipped dark room.

ventilated, equipped and furnished—in charge of a licensed pharmacist. Drugs and supplies are sent by the pharmacist by way of dumb-waiter to the nurse in charge of the various clinics. At the south (rear) is located the heating plant, janitor's storage, supplies, etc., and exit to large enclosed area.

First Floor.—North is the main entrance to the clinic, through enclosed hallway. Immediately to the left is the office of the registrar. Here all applicants are interviewed, records made, filed, and information given, also general supervision exercised by registrar. Immediately adjoining this room, and to the left, is the office of the social service nurse. To this nurse is assigned the usual duties in connection with social service and follow-up work. The entrance and these offices occupy the entire front on this floor. Large, conveniently arranged and well furnished general waiting rooms are centrally provided. At the south end are toilets and wash rooms, together with small isolation room and rear exit, also telephone service.

Second Floor.—Patients are assigned by nurse from the general waiting rooms to the clinic waiting rooms, as requested by the chief of clinic or his assistant. Extending along the north of the second floor are the clinic rooms for medicine and

pediatrics (three rooms). Intercommunication is afforded from one room to another, also from each room to the waiting room. Extending along the south end of this floor are the clinic rooms for surgery, gynecology, obstetrics, and neurology (three rooms), and waiting room. Utility rooms, closets, and wash rooms, are also afforded.

Third Floor.—To the north are clinic rooms for eye, ear, nose and throat (three rooms), together with waiting room and dark room connected with eye clinic. To the south are clinic rooms for genito-urinary conditions, syphilis, and dermatology—three rooms—together with waiting

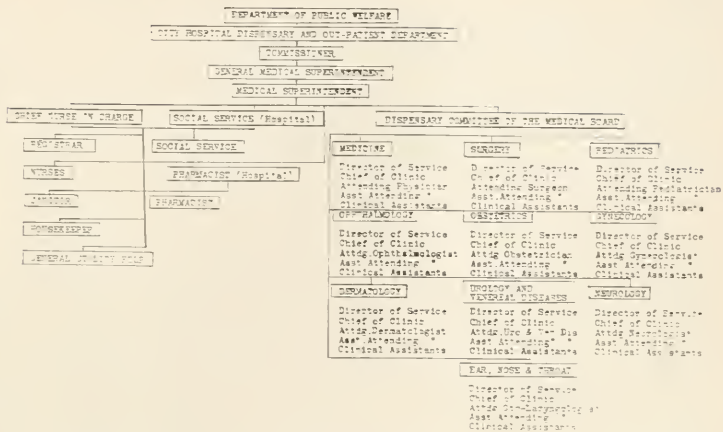

room. Utility rooms, closets, and wash rooms are also afforded.

Fourth Floor.—At the north a large well lighted, ventilated, and equipped laboratory extends along the entire front. At the south section, a suite of rooms for caretaker and resident help, together with two rooms for physicians, are provided.

A Noteworthy Achievement

The personnel assigned to this department have been carefully selected from among the nurses and doctors trained at the City Hospital, and the whole personnel constitutes a very capable, efficient and sympathetic staff. The dispensary organization is directly articulated with the corresponding organization at the hospital. Experience shows that this organization is logical, direct, efficient, and we believe represents the modern organization of a dispensary operated in connection with a large general municipal hospital. Patients requiring x-ray, special laboratory, and dental work are referred to the hospital as are also laboratory specimens other than called for in the routine work, such as smears, urine, sputum and stools. The nurses assigned to this service reside in the nurses' home, on the hospital grounds. Transportation is provided for them in enclosed car, morning, noon, and night. There is kept in the registrar's office a daily attendance record of the professional and administrative personnel attached to the dispensary, and we propose in the near future to hold monthly medical staff conferences.

The Dispensary was formally opened July 24, 1922. The number of applicants, general and special treatments, operations, advice, and relief

Plan of organization and authority of personnel. The scheme definitely places authority and facilitates the service assignments.

Section of one of the surgical clinic rooms.

given, represents a steady growth. Furthermore, patients requiring hospital treatment, particularly tonsils, adenoids, bow-legs, and eye conditions, have been referred to the hospital, and patients are frequently discharged from the hospital, and referred to the dispensary for subsequent treatment, thus shortening the period of hospitalization.

The chart appended shows the plan of organization and authority. This is definite, compact, and directly places responsibility and authority. As a working plan this scheme is as near the ideal as any thus far promulgated. Each member of the administrative and professional staff is provided with a copy of this organization chart, the service assignments, and rules governing the operation of the dispensary.

With the dispensary as a nucleus, the good that is in the human heart can shine out into the homes of the poor and sick residing in the community. Here we are endeavoring to cultivate the spirit of service, to teach preventive medicine and hygiene, to prevent diseases, to alleviate and cure disease, to afford relief, and to follow up needy cases. With all, to educate and deal sympathetically with the needy and deserving dependent sick and injured. In brief, it is our desire to make this a model, municipal, hospital dispensary and out-patient unit.

Psychiatric Social Workers Organize

Psychiatric social workers through the country have organized as a section of the American Association of Hospital Social Workers, to be called the Section on Psychiatric Social Work. This action, planned and discussed, at the time of the National Conference of Social Work in Milwaukee, 1921, was put into effect during the 1922 Conference at Providence, when the American Association of Hospital Social Workers at its annual meeting formally adopted the section.

Active membership in the Association includes those that have been employed for a year in social work in a hospital or dispensary. Social workers employed in clinics not associated with hospitals or dispensaries or with mental hygiene societies are admitted to associate membership. The requirements for active membership in the newly organized section are based on training and experience, and there are no associate members. Graduates of recognized training courses in psy-

chiatric social work of not less than nine months duration are eligible after they have held a position in psychiatric social work for one year; graduates of schools of social work who have not taken a special course are eligible after two years in a position in psychiatric social work; and persons who have not taken formal training but met certain educational requirements are eligible after four years of successful accomplishments in psychiatric social work.

The objects of the Section are (1) to promote association of psychiatric social workers and (2) to promote standards in psychiatric social work. Meetings of the Section will be held when the Association holds its annual meeting during the Conference of Social Work in Washington, May 16 to 23. The president of the executive committee of the new section is Mary C. Jarrett. Inquiries of all kind may be addressed to the secretary, Mrs. H. C. Solomon, 74 Fenwood Road, Boston, Mass.

Bedside Care by the Municipality

Merrill Champion, in a discussion of nursing service (*P. H. Nurse, Feb., 1923*) says that "Plain common sense as well as logic leads to the conclusion that the path of wisdom lies in the

direction of two types of service; one educational, under the board of health; one, bedside nursing under a private agency, the latter of course doing all the educational work it can in connection with its work of treatment." The article is an interesting brief for the above statement which closes a paper advocating a system opposed to the recommendation of the report of the Committee on Nursing Education of the Rockefeller Foundation (*Nation's Health, July 1922*) in favor of generalized nursing service.

Health Score for School Children

Believing that school children should have some health standard toward which they may strive, Clark and Lowry have prepared a score, (*Pub. Health Rep., Feb. 16, 1923*). Opposite each child's name on the health chart is placed a red star in the column marked "Eyes" if on the first examination the child's vision is up to the specified standard. If the vision is found defective but later corrected the child is then entitled to a blue star. Similar markings indicate the status of the child in relation to ears, nose, throat, mouth, skin, chest, vaccination and nutrition. When every space is filled the child receives a gold star.

Hamline Church Health Center

Underwood & Underwood
The mothers in the neighborhood of Hamline Church, Washington, D. C., who have food problems or other difficulties in rearing their children which require expert guidance, can find the necessary supervision at the Hamline Church Health Center, whose practical interest in welfare has taken the form of a community health enterprise.

The Teaching of Hygiene to College Students*

Being a Committee Report to the American Student Health Association

By DR. JOHN SUNDWALL, PROFESSOR OF HYGIENE AND PUBLIC HEALTH, UNIVERSITY OF MICHIGAN, ANN ARBOR, MICH.

AT THE annual meeting of the American Student Health Association held in New York City, December 26, 1921, a motion was unanimously carried that the president appoint a committee of five to consider the subject of hygiene teaching in colleges and universities, and to recommend to the Association the contents of a general course in hygiene which would be of greatest value to the average college student. According to the secretary, "the committee should concern itself with the contents of a course in college hygiene, giving a practical working scheme, methods of presentation, and number of hours devoted to the subject." The committee was instructed to make a report at the annual meeting of the Association to be held in New York City, December 26, 1922.

President Raycroft appointed the following committee: Drs. T. A. Storey, College of the City of New York, T. A. Devan, Rutgers College, E. Esquerre, Carnegie Institute, A. Kerr, Cornell University, and J. Sundwall Chairman, University of Michigan.

The committee submits the following report:

Obligations to Teach Hygiene

When a university or college confers a degree it underwrites the young man or the young woman on whom the degree is conferred. It says to society, "Here is one who is fitted to serve or lead intelligently." But service or leadership on the part of the graduate will depend on the energy that his body machine can generate and maintain. Society is cheated if the college underwrites an impaired human motor which will break down soon after it enters the traffic of life. Therefore, it is imperative that an educational institution concern itself with helping its students build up and keep up high-powered, efficiently running, energy-generating motors of the first magnitude, and that it teach them how to maintain these—that is, how to keep up health and physical efficiency through college years and

through the years of service ahead of them.

The college student should be well grounded in the fundamentals of health promotion and disease prevention, not only for his own preservation and efficiency but also for the welfare of society in which he will serve later on. College students usually become teachers or leaders in their communities. Therefore, it is imperative that each student should be given a clear grasp of what is essential and worth while in community health work.

With a view of meeting these obligations, the committee recommends that the American Student Health Association urge all colleges and universities to adopt and put into practice a scientific and systematized course in hygiene. The committee recommends further that this course be made a requirement for all college students and that it be taken by college students as early in their academic career as possible—preferably the freshman year.

Extent of Course.—The length of the course—one or more terms, and the number of hours per week, must of necessity be determined by local conditions. Some institutions now devote seventy-two hours of class work to this subject. The other extreme is seen in those colleges and universities where no hygiene is given. Between the two, there is every gradation. It would be unwise to recommend a maximum number of hours since there are practically no limits to which the study of hygiene and public health can be made profitable. It is with the minimum number of hours that we should be concerned. The committee, therefore, recommends that this minimum should be two hours per week for one semester or three hours per week for one trimester or quarter. The total number of class room hours then would range from thirty to thirty-six. It should be emphasized here that more time than this could be used advantageously.

Presentation.—A course in hygiene to college students should be made as scientific, practical, and definite as possible. It should be fully illustrated

by charts, models, lantern demonstration, and by experiments. For each hour of class room instruction, two hours of outside preparation—home or library study—should be prescribed. Lecture notes should be handed in and graded. One mid-term and a final written examination should be required in order to pass the course.

The same study, intelligence, dignity and respect should be accorded the presentation of college hygiene as are now generally given to the teaching of the other sciences in the college. Instructors in hygiene should be chosen with the same care and consideration of training and teaching ability, as are instructors in the other sciences. Similar academic rank and dignity should be accorded to the teaching staff of the department of hygiene as are accorded to the teaching staffs of other departments in the college.

The department of hygiene should be closely correlated with other interests and activities concerned with the health of students. A student health service offers an unusual opportunity for acquainting students with the machineries of modern public health. One may, therefore, regard the student health service, where established, as an immensely important teaching instrument or laboratory. Departments of hygiene in college should use their influence toward establishing efficient health services where these do not exist.

Size of Classes.—The same regard for efficiency of instruction, with particular reference to the number of students enrolled, must be held for courses in hygiene as for instruction in the other sciences. For the lecture work, a large number of students could be brought together, but for quizzes and other work in connection with the course this large group should be divided into small sections.

Essentials of Course

The Committee feels that the content of the course should be such that it would acquaint the average college student with the fundamentals of (1) health promotion and (2) disease prevention, both from the standpoint

*Presented before the fourth annual meeting of the American Student Health Association, Detroit, Mich., December, 1922.

of the individual and the community.

(1) By health promotion is meant the building up and the maintenance of a sound, active, vigorous and harmoniously developed body. Other synonymous terms used to designate this phase of hygiene teaching are "personal hygiene," "individual hygiene," "physiological hygiene." The objectives to be reached in the teaching of health promotion are (a) to inculcate in the student an impelling and lasting desire to achieve and maintain positive health and physical efficiency and (b) to acquaint him with the various methods by which these may be gained.

The student must be made to realize that, like an automobile, his own body may be ready for the "scrap heap" in a short time or it may be made to run smoothly and efficiently for an indefinite period; that the outcome will depend largely upon his knowledge of the structure and functions of his body machine and the intelligent care he gives to it; also that every individual making up a community should be given an opportunity to develop and maintain positive health, both for the well-being and happiness of the individual concerned and for the economic efficiency of the community.

The fact must be emphasized that *positive* health does not mean merely freedom from disease, but the best possible physical condition, the greatest possible capacity for activity, happiness, and physical efficiency.

(2) In the field of disease prevention the student must be impressed with the fact that no matter how intelligently and vigilantly one may develop and maintain the best physical condition possible, this does not prevent one from contracting communicable diseases if exposed to them—that if one's cook or one's waiter in a restaurant is a typhoid carrier or one's bed-fellow has active tuberculosis, or the fellow at the next desk in the office has diphtheria, these diseases may be readily contracted no matter how healthy one may be. The necessity of both individual and community concern for disease prevention must be emphasized, and the necessary measures for disease prevention and control brought out.

Contents of Course

It is not the purpose of the committee to present here a detailed syllabus on hygiene teaching. The details of a course must necessarily be left to the intelligence and discretion of the teacher. Again there is danger of over-standardization. Many factors

will determine, in a large measure, the details of a course in college hygiene and the emphasis placed thereon. The number of hours allotted to college hygiene, the geographical location of the college, prevalence of endemic diseases, communicable diseases peculiar to the locality, urban or rural location of the college, environment of the college, chief industry of the section influenced by the college, seasons, and so on—all are factors which will necessarily influence the order of presentation, the details of, and the emphasis on a college course in hygiene.

There are, however, certain fundamental matters concerned with health promotion and with disease prevention that should be presented and emphasized in every course in college hygiene.

I. The following objectives should never be lost sight of in any college hygiene course:

(1) Instilling in every student an impelling desire for positive health and physical efficiency, not only during student days but in later years as well—both for his own happiness and success and as an obligation to society from the standpoint of economic independence and service to society.

(2) Appreciation by each of his responsibility and need of concern for, not only his own health but that of others making up his community and inter-relation of these.

II. *General Considerations.* (1) Past attitudes and activities towards health and disease: Brief historical references to "demonological" and "punishment by God" theories and attitude of resignation; filth and spontaneous generation theories; era of environmental regulation and sanitation; era of Pasteur and bacteriology—defensive era; followed by era of fighting disease—offensive attitude; past public health activities concerned almost entirely with the prevention and control of diseases.

(2) New conceptions of health interests and activities: (a) Positive health and physical efficiency—in addition to fighting disease, a new and important objective in hygiene and public health. Differentiation between positive health and absence of disease. (b) Differentiation between health promotion and disease prevention.

III. *Health Promotion.* Personal, individual or physiological hygiene. Facts or matters which the individual himself must know and must practice in order to maintain positive health and physical efficiency.

The "Health Promotion" aspects of the subject may well be considered

from two standpoints: (A) General measures that concern the well-being of the body as a whole and, (B) Special hygiene of organs and systems.

We have gained sufficient information through studies of the findings of group physical examinations—draft, schools, industries, insurance, etc., and through analyses of our national morbidity and mortality statistics, to warrant the recommendation that the general measures be given adequate consideration and emphasis. There is danger that when health promotion is presented entirely from the viewpoint of special hygiene of systems and organs, unimportant details will be emphasized and the knowledge gained will be more or less fragmentary and therefore not interrelated. However, it is very difficult to draw any line of demarcation between general measures and special hygiene of systems. Many of the former are more or less tied up with the latter. Furthermore, many teachers prefer to present these general measures in connection with the systems of the body and vice versa. The general measures are, therefore, set apart solely with a view of calling attention to their importance.

(A) General measures: (1) Food and nutrition: The balanced diet, quantitative and qualitative daily needs, including water, weight, overindigestion, undernourishment, deficiency diseases. (2) Air. Ventilation, temperature, humidity, air in motion, air pollution, climate and health. (3) Physical activity and exercise: Strength, endurance and fatigue. (4) Rest and sleep. (5) Bodily poisons: Endogenous and Exogenous—with particular reference to focal infections, auto-intoxication, alcohol, drugs, patent medicines. (6) Degeneration diseases. Role they play in our nation's morbidity and mortality. (7) Shelter. Home construction, clothing. (8) Mental hygiene: Emotional instability, psychoses and neuroses, rationalization, social adjustment. (9) Prevention and correction of bodily defects. Studies of draft examination, school examinations, of other age groups. (10) Physical examinations—Annual overhauling: Its importance in relation to the early detection of the degeneration diseases. Its relation to life extension and longevity. (11) Sex Physiology and Hygiene: Sublimation of sex thought, imagination and desires, continent life and the single standard of morality, penalties of illicit sexual intercourse. Venereal diseases. (This as well as (13) may follow B. 4)

(12) Heredity and Eugenics: Role of heredity and environment, Mendel's Laws, transmission of defective qualities, etc. (13) Cancer and Goiter, especially where it is endemic, may well be regarded as important consideration for the health promotion aspects of a course in college hygiene. (14) Accidents and Injuries: "Safety first" and first aid.

(B) Special hygiene of systems of organs. (1) Digestive system, oral hygiene. (2) Respiratory system. (3) Skin and appendages. (4) Genito Urinary system. (Sex hygiene may be considered here.) (5) Special senses: Eyes, ears. (6) Skeletal system with particular reference to posture, feet. (7) Cardiovascular system. (The degeneration diseases may be well introduced here.) (8) Muscular system: The general measures of exercise and activity may be considered here. (9) Nervous system. (Mental Hygiene may be presented here.) (10) Glands of Internal Secretion.

Just how much emphasis should be placed on the anatomy and physiology of the various systems of organs must be left to the teachers' discretion. The various training of the student, among other factors, should be taken into consideration. At any rate, care must be taken not to weary the student with unimportant and burdensome details in anatomy and physiology. This has been the chief fault with our past attempts at teaching personal hygiene. Furthermore, there is danger of placing too much stress on non-essentials and minor matters. We must bear in mind that there is no other subject in the curricula of schools and colleges which is so saturated with empiricism and fadism as is personal hygiene. The truth is that we still know comparatively little relative to the hygiene of organs and systems of organs in general. It is imperative that only the important and really known and accepted facts be emphasized.

IV. *Disease Prevention* (Group and Community Health) with particular reference to the prevention and control of communicable diseases. This would naturally follow the health promotion aspects. It might be, however, that, owing to the presence of epidemics or to certain local conditions, the presentation of communicable diseases and community health should precede "Health Promotion." Again occasions may present themselves at any time during the course which would call for a consideration of community health.

(1) Nature of communicable diseases: (a) Historical conceptions, mi-

asmatic theories. (b) Germs—nature of, classification, distribution; pathogenic organisms—bacteria protozoa, parasites. (c) Epidemics and pandemics, some historical considerations.

(2) Source of disease: Generally speaking man is the chief source, animals infrequently. Disease kept alive in community by carriers, missed cases, prodromes, convalescents; passed from infected individual to another by means of contact infection.

(3) Diseases spread by: (a) Discharges from mouth and nose. (b) Alvine discharges. (c) Discharges from lesions. (d) Blood transfers (Yellow fever, malaria, etc.).

(4) Contact Infection. Direct, indirect.

(5) Routes taken by Communicable Diseases. (a) Close Social Contact, the broad paved highway over which the important diseases, especially in our latitude, travel. (b) Water. (c) Milk. (d) Food. (e) Insects and animals.

(6) Blocking the routes taken by communicable diseases. (a) Diseases for which we have special or specific prophylactic treatment. Special consideration of Immunity, Vaccines, Vaccinations, Serums, Specific drugs, etc. Relation of animal experimentation and vivisection to progress in curative and preventive measures. (b) Close social contact and intercourse: Difficult to block as people object to laws regulating their personal behavior unless they understand the significance of these laws. Hence education of masses along the lines of contact infection, with a view of avoiding or minimizing the dangers thereof is the first essential in blocking this route; values of isolation, quarantine, handkerchief, masks, clean hands, etc. (c) Water: Boiling, storage, filtration, chlorination, etc. (d) Milk: Certified and inspected milk, tuberculous cattle, handling and shipping, pasteurization. (e) Food: Dangers of carriers infecting raw foods, hence examination of food handlers, food infections, meat infection, canning, food sterilization, etc. (f) Insects: Destruction of flies and other insects, privies, drainage and oiling of swamps, insecticides, destruction of disease carrying animals, etc. The important progress along these lines.

The committee feels that if due consideration and emphasis are given to these various topics as suggested in this outline of a college course in hygiene, the student should have a general grasp of important factors that, if wisely applied, will contribute to his health and welfare and that of his

community. Experience has shown that these facts can be amply presented and considered in a course of from thirty hours to thirty-six hours including outside preparation.

When the time allotted is sufficient the principles and practices of applied hygiene may well follow the general consideration of the principles of health promotion and disease prevention.

V. *Applied Hygiene*. By applied hygiene is meant the application of the principles of health promotion and disease prevention to certain age periods, units or groups of society. The application of these principles are modified and adjusted in order to meet the particular needs of these age periods or groups. (1) Child hygiene. (2) School hygiene. (3) Adult hygiene. (4) Industrial hygiene, with particular reference to occupational diseases. (Of particular value to college students who later on in life will become factory administrators.) (5) Rural sanitation. (6) Urban sanitation. (7) State, national, and international health measures. (8) Vital statistics: Bookkeeping of health of community and its importance.

Further, it would be well to acquaint the student with the various agencies or machineries engaged in health work. (9) Official Health Departments. Functions and Activities of (a) city, (b) county, (c) state, and (d) federal. (10) Voluntary health departments. How these function and can be utilized. (a) Red Cross. (b) International Hygiene Board. (c) National Tuberculosis Association. (d) American Public Health Association. (e) The more than eighty national associations which deal with the various aspects of applied hygiene.

Most of the "co-eds" at the University of Texas who are working for a letter in athletics this year have pledged themselves to observe "Hygiene Month" in order to obtain extra credit. In making the letter awards, a point system is followed by which credit is given for athletic training done by women students under the auspices of the Woman's Athletic Association. By observing Hygiene Month, the girls pledge themselves to eat three regular meals a day and nothing before or after meals except milk, fruits or malted milk. Other requirements are, at least an hour's exercise a day, a daily bath and shower, and eight hours sleep six nights a week. At the end of the month if the candidate is able to state that she has not violated any of the rules, thirty points are placed opposite her name on the athletic record.

Steps Forward at the School for the Deaf*

By W. S. CAMP, EDITOR OF THE ADVANCE, JACKSONVILLE, ILL.

WITH the advent of Col. O. C. Smith as managing officer of the Illinois School for the Deaf late in October, 1921, there was inaugurated an era of progress probably unprecedented in the history of the school, which is the oldest state institution in Illinois.

Reorganization of the school proper, as well as changes of importance in the physical equipment of the institution, have been effected, and many further improvements are contemplated, depending largely upon the action of the legislature as regards appropriations for their carrying out.

The forces of the institution were reorganized in a manner calculated to bring about efficiency of operation and to place responsibility where it always should have been—upon the shoulders of those in charge of the several departments. The institution was organized into seven departments for the purpose of administration. The departments were as follows: the school department, the clerical and supply department, the household department, the engineering department, the farm and dairy department, the social welfare department, and the hospital department. Through the operation of the new organization with responsible heads in charge of each department, the managing officer is in a position to place responsibility for the progress and welfare of each department; and in addition he is so placed as to avoid the annoyance of the countless petty details which are so common to the administration of the affairs of state institutions. Under the new system all details are given attention by the heads of departments and matters are not presented for the consideration of the managing officer unless discord or other intervening handicap develops, or their importance justifies his attention. The new system has worked well and the results attained have in every way justified the inauguration of the plan. The School for the Deaf is primarily a school, and every endeavor is directed towards enhancing its value as an educational institution. This aim has been impressed upon all officers, teachers and employees of the institution.

One of the most important outside

works connected with the school is the effort put forth to secure the attendance of all the deaf children of the state who are of school age, which under the Illinois statutes is from seven to eighteen years. In this endeavor is engaged the head of the social welfare department, Miss Grace E. Hasenstab, thoroughly familiar with the deaf, who devotes full time to looking after the deaf children and taking an interest in the welfare of the deaf of the state whenever her services are requested.

The attendance at the school is now larger than it has been at any time during the last decade and it is believed the number of pupils enrolled will soon be more than 450. Many of these children are new pupils and a great many of the first-year group are in the school as a result of the efforts put forth by the social welfare department. The interest of the social welfare worker does not conclude with the arrival of pupils at the school; she is busily engaged in behalf of the children at all times. She acts as interpreter, visits the school-rooms as occasions require, assists the literary societies in their work, attends to much correspondence with parents, and looks into home conditions in cases which justify investigation. She also is charged with giving attention to problems relating to the welfare and success of pupils going out into the world after their school days are ended. She is the means of communication between the school and the home relating to the health of the pupils.

The school department is the most important of all. Its curriculum includes the common school branches taught in the public schools. In addition there is given opportunity to perform shop work calculated to enhance the chances of those going out from school to make a living. The school also supports a class engaged in post-graduate work, intended to equip the pupil for entrance to Gallaudet College at Washington, D. C.

There are maintained in connection with the school several shops designed to give girls and boys working knowledge of trades and vocations. These shops include a well equipped domestic science department, a sewing department, a millinery department, an art department, a photographic studio, a shoe shop, a wood working shop, a paint shop, a bakery, and a print shop. There is organized and in working trim a class in the machine shop under the direction of the chief engineer. A class in farm and ganization. Other lines are soon to be added, including concrete construction work. All of the shops are well equipped with the modern machinery and tools desirable in a first class working establishment. At the head of each of these shop forces is a teacher qualified for the work.

During the last year the faculty of the school has been reorganized. The resignations of the eight teachers accepted by the managing officer at the close of the last school term. These places have been filled by teachers who have had special training for the work or those experienced in teaching

Health Conservation Through the Ages*

Nearly All Die Prematurely. Only the Exceptional Person Lives a Normal Life to Its Conclusion

By EUGENE R. KELLEY, M.D., STATE COMMISSIONER OF HEALTH, BOSTON, MASS.

TO PRESENT a comprehensive picture of what is implied by the extremely common term "conservation of health" is a difficult matter. When this topic is under consideration we are not dealing with something to be weighed by the ton, measured in board feet, or calculated in kilowatts, but with a subject whose inherent qualities defy exact measurement or even precision of definition. It is a subject concerning which, curiously, almost everyone has some rather definite convictions, but one in which the formulae of one group may be entirely rejected by another group. As soon as the value of a scientific fact in preventing disease or increasing vitality has been adequately demonstrated, one type of human mind concludes that this fact or discovery ought to be forthwith applied to the entire population willy-nilly. But there also exists another type of mind that tends to consider all health work as partaking in varying degrees of the faddish in quality and to look with skepticism upon all alleged advances in health conservation.

Between the two extreme views, that of the impractical enthusiast on the one hand and of the sanitary cynic on the other, must lie the real, solid field of accomplishment in health conservation. There is, an actual danger from unbridled enthusiasm in health

Obviously there is sufficient scientific knowledge extant, if intelligently and universally applied, to prolong the average human life many years, and to make all these years much more abounding with the joy of living that accompanies top notch physical condition than is the case with the average person to-day.

Whereas the average American life expectancy is now probably in the neighborhood of fifty years, there is no insurmountable obstacle in sight to increasing that average expectancy by at least twenty years in the next four generations. Surely this is a goal worthy of public health work.

conservation proposals. It is conceivable that human life might become so completely safeguarded against accident, infection, fatigue, systemic toxemias, or mental and nervous strain that existence itself would become so monotonous and boring as to be almost not worth while to a large proportion of individuals. On the other hand, the carrying out of the doctrine of individual "self determination" to the extent of refusing to admit the truths of science or of refusing to admit the existence of any obligations on

the part of government to citizens, parents to child, employer to employee, or individual to the community, in health matters, is a terrible thing to contemplate. Yet there are elements in our national life, some active, noisy, self-seeking, others earnest and fanatically sincere, who unite in propaganda whose objective is nothing less than the destruction of all governmental or organized private efforts for the conservation of health.

Health conservation has one underlying peculiarity which is shared by only a few of the other subjects concerning which conservation is a live issue. The conservation of health can never be completely achieved in its broadest sense by statute or by the expenditure of money alone, important as both these considerations are in any sane national health conservation program. The conservation of health depends in the last analysis upon the conscious desire and conscious voluntary response to that desire by animate, free agent, human units acting sometimes collectively, sometimes as individuals.

It is noteworthy that this whole subject is of remarkably recent origin.

It has been aptly said that the only guide we really have in planning for or in predicting the accomplishments of the future is the experience of the past. Only by tracing back to its beginning can the present structure of health practice be properly evaluated, present problems seen in perspective,

*Read before the American Association for the advancement of Science, Boston, Mass., December 27, 1922.

or future trends even tentatively predicted.

Down to relatively recent days two prevailing theories fought for control of communal and personal health policies. The one that gradually predominated and settled for centuries like an incubus over all attempts at advance was the theory or belief that all illnesses, pestilences and deformities were a direct manifestation of Divine wrath and hence that it was nothing short of impiety to make any attempt towards their control. This theistic point of view reached its climax in the latter middle ages and is perhaps nowhere more graphically expressed than in the words of an orthodox physician of the city of Reggio, Italy, when the reigning dukes, (brothers and apparently men in advance of their times) during a plague epidemic, introduced the revolutionary procedure of forced isolation of the sick from the remainder of the people, with the further drastic provision that if any parish priest or civic authorities failed to report cases coming to their attention *at once* they should suffer the death penalty. All this occurred in the year of our Lord, 1374, and the comment of the orthodox physician of that day is as follows, "And I saw in this same year that these orders were observed in Reggio for *which cause* all were more grieved and terrified than by the fear of the pestilence, which, *when God permits it*, cannot be arrested."

The type of mind which sought for rational and natural causes as an explanation of pestilences and epidemics was always hopelessly handicapped by the lack of any concept of the nature of microscopic life. Hence for centuries the scientific world elaborated and discussed theories of "miasmas," "atmospheric corruption," and the like which make pathetic reading today in their blind gropings for a natural explanation of the destructive whirlwinds of epidemic disease which periodically devastated the ancient and medieval worlds.

Modern Methods Begin

Modern preventive medicine or hygiene may really be said to date from the discoveries of Pasteur in the world of bacteriology. It was not until the late 80's of the last century that the leaders of clinical medicine in either Europe or America can be said to have generally accepted, with all the revolutionary implications contained therein, the demonstration of the existence and practical significance in health or disease of the bacteriologic world. Principles of modern sanitary

engineering were already being steadily applied with notably beneficial results in matters of housing and community sanitation, but the demonstration concerning the micro-organic world was soon put to practical utilization in water and sewage filtration by sanitary chemists and engineers. One great plague, typhus fever was placed under control during the earliest stages of modern sanitation. It might almost be said that like Hercules, the infant science of sanitary engineering while in its cradle throttled this monster, even before it was old enough to comprehend the significance of its efforts.

Without attempting to follow chronological sequence or to place any emphasis as to their relative weight as factors in our present day body of public health practice, several elements entering into the modern health movement deserve passing reference. All have played a definite part in our achievements in these directions. Some of them are exclusively concerned with health conservation; others have come into play as a result of economic or social advance and their great health significance has often been entirely overlooked even by life long students of sanitary science.

The Educational Factor

Foremost among these is the growth of modern education. It is sharply questioned today by some whether our modern system of universal literacy and diffusion of information really constitutes education. One brilliant student of human affairs in an article recently contributed to a leading American magazine frankly takes the ground that we have made no real advance over Hellenic civilization in true education. Be that as it may, I firmly believe that modern public health achievements would have been utterly impossible save by imparting a rudimentary understanding of modern sanitary science to the masses in schools and by our books, papers and magazines. Lacking an at least partially-informed public opinion in these matters, progress in modern health endeavor would have been far below its present mark. The remnants of ancient and medieval pseudo-science transmuted into the superstitions, folk lore, and "old wives' tales" of modern times still remain one of our greatest obstacles to the more universal acceptance and application of the life-saving principles of hygiene. If the influences of our modern school systems and the dissemination of knowledge generally by books and periodicals were not partially neutral-

izing the subtle mischief of these inheritances of barbarism and superstition, the passive resistance offered thereby to the progress of hygiene would be almost insuperable.

Insects and Disease

A prominent place among the factors of modern health development must be reserved for the far-reaching discoveries of the relationship of the insect world to disease. The knowledge of the relationship of the mosquito to malaria and yellow fever, and of the flea to bubonic plague, to cite outstanding examples only, has been of great significance to all of us, and not only has this knowledge resulted directly in great saving of human life, but indirectly it has meant much already and in the future cannot help but mean vastly more in greater freedom of intercourse and trade among nations, and in the opening up of vast areas of the world's surface to agricultural or other uses.

A matter usually ignored in consideration of the factors of health conservation is the matter of food supply. Without considering the problem of personal nutrition or proper balance of metabolism, the thought it is desired to bring out here is the hygienic importance of having enough food of sufficient variety produced and distributed at a cost which the masses can meet. Here is the true course of much of the happy results of modern life-saving for which we are altogether too prone to give credit exclusively to the laboratory and microscope, the surgeon's knife and the physician's pill. Among the many startling object lessons of the great war none has been more dramatic than the revelation of what a period of widespread inadequate nutrition means in the morbidity and mortality tables of a nation or community. In looking back we see plainly that it was the recurring famines, followed always by fearful pestilences, which largely account for the almost incredible mortality rates of the middle ages.

Food Factors in Health

Modern health work is under a tremendous debt of obligation to those discoveries in soil chemistry, and to both animal and plant breeding and to the invention of modern agricultural machinery, which together have resulted in the present standards of quantity and cost in the matter of food production.

Bountiful production of food at reasonable cost is not by any means the whole tale of the fundamental bear-

ings of the subject of food upon health. Transportation and preservation of food by various devices have played a large part in making possible the all-year-round supply of a dietary adequate for the maintenance of the metabolism of the masses on a basis never before remotely approached. Rapid transit, modern canning processes, cold storage have all contributed to this phase of advance in health conservation.

Improved Living Standards

Another factor which has entered largely into the evolution of better health standards has been what is commonly comprehended by the phrase "standards of living." This is an expression which does not lend itself well to exact definition. It implies matters of esthetics as well as matters of sanitation. Such details as increased facilities for recreation and exercise, better ventilated, heated and lighted houses, workshops and buildings devoted to commercial, educational and amusement purposes, have contributed much to the conservation of our health.

A factor in the gains of our era in health promotion and life prolongation that cannot be ignored is the economic or more often the combined economic and sociologic factor. A leading American public health authority¹ concludes a recent critical study of the causes of our present striking decline in tuberculosis deaths with the statement that the improved earning capacity and shorter hours of labor of the average American wage earner have contributed more to this decline than all the institutional and medical care and general educational aspects of the anti-tuberculosis movement combined.

Both the amount of compensation of the worker and his hours of toil are of deep significance in determining the general health of the community. It is also true that specific safeguards against the hazards of industry are a prominent part of any health conservation program. From industrial stress and strain, from extremes of temperature in industry, from dust, smoke and fumes, from undue general or local fatigue come much physical impairment, shortness of life, industrial inefficiency and community impairment. The rapid growth of the science of industrial hygiene has been the answer of industry to the significance of these discoveries.

Having considered a few of the most important underlying contribu-

tions to health advancement it is now appropriate to weigh the significance of those factors usually thought of when the terms "health work" or "preventive medicine" are used. Reference is meant to the direct bearings of research in pathology, bacteriology, physiological chemistry, entomology and their newer subdivisions, together with the contributions of clinical medicine and epidemiology proper to the subject of health conservation as weighed and evaluated by the methods of vital statistics. This is what is commonly meant when the term "public health" is used.

Step by step with these discoveries has grown up during the past fifty years a remarkable number of agencies designed to function exclusively for the preservation of human health. Many of these are regularly constituted departments of national, state, and local governments.

Side by side with these health departments have also gradually come into existence a host of non-governmental agencies whose objective is the promotion of health. These range all the way from the vast endowed organizations, as the International Health Board of the Rockefeller Foundation, for instance, with a budget and resources far in advance of practically all governmental health departments down to the smallest village's band of public-spirited women who have united to ensure the services of a home visiting nurse for the community. In the promotion of health the aggregate influence of these organizations has been tremendous.

Statistical Record

Now let us see very briefly what the record of fact shows in the gains of health conservation up to the present. To present an elaborate statistical analysis as a basis for this statement, interesting though it might be, would unreasonably prolong this paper, hence merely a few salient features of Massachusetts' experience will be cited, with the general qualification that they may be accepted as typical of all localities where the occidental type of civilization prevails.

In Massachusetts the average yearly death rate from all causes from 1885-88, inclusive, was 19.5 per 1000 population; for 1920, the rate was 13.9 per 1,000. This means over 20,000 more lives were prolonged in comparison with the rate of about thirty years ago.

The infant mortality rate of Massachusetts in 1885 was 156; for 1921 it was 76. This means that whereas in 1885 a new-born infant had only a

little better than five chances in six of living to celebrate a first birthday, now less than one child in ten dies under the first year, a most creditable gain but still a fatality hazard much higher than we know to be necessary.

The death rate for pulmonary tuberculosis in 1885 was 307 per 100,000; in 1920 it was 96 per 100,000. This means that if the tuberculosis death rate had remained today what it was in 1885 in place of approximately 3,300 dying this year from consumption the number would have been over 12,000.

In 1885 the typhoid death rate of this commonwealth was 39 per 100,000; in 1920 it was 2.5. This means that, whereas less than 100 Massachusetts people died from typhoid in 1920, had the same rate prevailed as in 1885, 1,560 would have died.

In 1885 the death rate for diphtheria in Massachusetts was 78 per 100,000 of population, in 1920, 15 per 100,000 population.

In 1885 the death rate of scarlet fever per 100,000 population was 30.2. In 1920 it was 5.5 per 100,000 population.

Or it is perhaps more graphic and comprehensible to reduce the matter to terms of average expectancy of life at birth.

In 1885 the average approximate expectancy of life for a new born baby (male) in Massachusetts was 42 years (female), approximately, 43.5. Both sexes average 42.75 years. In 1920 the average expectancy was 53.98 years (male); 55.33 years (female). Both sexes 55.1 years.

Upon reflection we can see that up to a period roughly coincident with the end of the first decade of the present century all the influences operating most prominently in connection with health conservation have certain features or characteristics which mark them off to a certain extent from the health conservation problems of the present and near future. In general it may be said that hitherto the greatest emphasis has been placed, and the greatest advances made in the field of infectious disease prevention and control. It is also quite obvious that except in the case of the infectious diseases such gains as have been made in promoting the health of the individual or the mass have often been due to the accidental or unexpected results of some improvement in industry or transportation or the result of increased community interest in recreation or sociological endeavor, rather than to a conscious deliberate attempt to im-

¹ Emerson, Haven: The Factor of the Declining Death Rate for Tuberculosis, *Am. J. Tuberc.*, 1922.

prove the health of the individual or community. It may also be said with a high degree of accuracy that the health advances of the recent past have generally represented those things that could be *done* for the average citizen rather than those things which he *had to do for himself*.

As we turn to consider the future problems of health conservation we will note that all three of these factors will cease to be as proportionately effective as heretofore and must be replaced by procedures along radically different lines if the full potential benefits of a sound national health program are ever to be realized.

Present and Future

I have traced roughly some of the sources from whence our present health conserving agencies have sprung and have drawn attention to the crude proof of their accomplishments as registered in increased average longevity and decreased fatality from specific morbid processes.

Broadly speaking, no such results have ever been remotely approximated before in the world's history—Egypt, Hellas, Rome, India or China knew nothing like it in the days of their greatest glory. This record of achievement is one thing which sets our era on a pinnacle apart from the remainder of recorded human existence. To be sure, deep concern over the human misery arising from bodily affliction has long been a great moral force in the world but it is only in our own times that humanity's struggling aspirations for the alleviation of suffering have been translated into scientific achievement.

An outstanding feature of present day health aims is the degree to which they recognize how far the lengthening of average expectancy of life up to the present time falls short of the full possibilities to be attained as an outcome of a comprehensive well-rounded national health program. Past accomplishments in health improvement have consisted largely in triumphs over environment and in control of infections. In building up the well-poised body and in cultivating the serene mind we can point to no such clear-cut victories. In these respects some authorities do not consider that we can equal the actual accomplishments in personal hygiene that were achieved by the citizens of ancient Greece.

It should never be forgotten, however, in making such comparisons that the *free* citizenry of ancient Greece never represented more than ten per

cent of the total population. No records have come down to us relative to the hygienic conditions or mortality rates of the slaves and serfs who represented ninety per cent of the populations of antiquity. When proper allowance is made for the status of the slave in classical times, I am reasonably certain that our *average* achievement in personal hygiene today far surpasses the average standards of antiquity.

Most of our gains in life prolongation hitherto have been in channels where either correction of faulty environmental conditions or an interruption of the chain of infection was indicated. It is a peculiarity of these two types of health activity that they can be carried out to a large degree by the mere passive acquiescence of the bulk of the community. It is obvious that even where efforts and results in these directions reach the maximum there will still remain untouched large segments of the health conservation field.

An Expanding Concept

These never and as yet untouched or only lightly touched phases of health development call increasingly for active participation by the individual citizen, and this question of the reaction between the offerings of science and their acceptance by the average American citizen in the field of health promotion presents one of the most fascinating problems of our present day schemes of human government and social relations.

Today we are no longer satisfied with a mere negative definition of health. Health must mean something more than mere absence of acute disease. It implies a standard of personal vitality and physique that insures a positive enjoyment of existence due to a properly balanced, well exercised, smoothly functioning bodily mechanism reacting agreeably upon the mental and emotional processes of the individual.

One of the outstanding difficult problems of preventive medicine is that of bringing home the extent to which avoidable sickness, inadequate or improper physical training in childhood and preventable accidents all considered together, slow down our national productiveness; absorb time, money and energy that could otherwise be devoted to the greater expansion of a national cultural life; result in increased delinquency and crime; and in general add to the sum total of preventable human misery. I will not go into exact statistics on this point. The publications of the Na-

tional Safety Council present a mass of startling information as to the burden of preventable accidents; the publications in recent years of the various social welfare organizations and of departments of correction, probation and charities of certain states and cities show how direct and extensive is the relationship between delinquency and non-social behaviour on one side and physical deficiency or subnormal health on the other. We have begun to accumulate a certain amount of data on the magnitude of the burden imposed on society from occasional illness, a large proportion of which could be entirely avoided through sound intelligently applied systems of community, industrial, school and personal hygiene.

The British health insurance tables show that "at least 14,476,000 weeks work are lost on an average every year through sickness. . . That is to say, in *England and Wales there is lost to the nation every year*, among the insured population only . . . the equivalent of the work of 278,000 persons (working constantly throughout the year) . . . it is not only the working equivalent of 278,000 persons that the nation loses every year, but also the labor and expense involved in their care during the 14,476,000 weeks of their incapacitation. To this loss of time and capacity among the fourteen million insured persons, we must, to obtain the (total) national loss, add a comparable (and undeterminable) though presumably not so large proportionate loss, in respect to the remaining twenty-three millions of persons, including children."

The next finding of the British health insurance scheme is the one which opens up a wide range of discussion as to the reasonableness of this enormous aggregate amount of recorded sickness. It is reported that when the causes of sickness which result in this staggering amount of national non-productiveness are sought that the absences from labor due to serious diseases such as organic heart disease or tuberculosis, for example, are relatively few but it is what are generally known as the minor maladies such as functional impairment of digestion or of kidneys, neuritis, neuralgia, sick headache, decayed teeth, tonsillitis, bronchitis and common colds, "rheumatism," etc., that are the principle causes for which these persons seek medical advice and absent themselves from work. In the aggregate these "minor ailments" produce a truly formidable amount of suffering, sickness, idleness and loss of income. An exceptionally large proportion of

just such aliments is entirely avoidable by attention to personal hygiene. Hence we see that the preventive medicine of the future must seriously concern itself with this problem as well as with its present recognized duties in sanitation and communicable disease control.

This swing of the pendulum away from consideration of mass groups of the population and towards emphasis upon the health problems of the individual is very noticeable in all lines of health work and is the best evidence now available of the directions in which we may confidently prophesy that future developments of health work will lead us. The very nomenclature coming into common use to designate the major divisions of health activity with the word "hygiene, infant hygiene, dental hygiene, mental hygiene, for example, contrasts sharply with the older divisions with which we have long been familiar—sanitary engineering, epidemiology, vital statistics,—words indicating mass or group conceptions as sharply as the newer terms indicate the individual.

It will perhaps suffice to indicate some of the hygienic measures which can already be seen coming into prominence in health conservation and which must inevitably come into much greater prominence in the future.

It is obvious that everything pertaining to the health of the mother must receive attention if real health advance for the nation is to be achieved. The health of the mother is so closely interwoven with the health of the infant that almost instinctively we associate the terms maternal and infant hygiene. And as Sir George Newman pithily puts it, "Here is the source of the nation. From a physical point of view, what the mothers and children are the nation is and will be."

Passing beyond the period of infancy we find our hygienic nomenclature chiefly focused on the general term, child hygiene, and better to emphasize the methods by which child hygiene is to be fostered, such specialized terms as dental hygiene, school hygiene, physical hygiene or education, hygiene of nutrition and others not yet so familiar.

Passing on to adolescence and adult life still other terms are coming into wider use and into more intelligent comprehension by us as a nation. I refer to such terms as mental hygiene, industrial hygiene, personal hygiene and all they imply. This list is not by

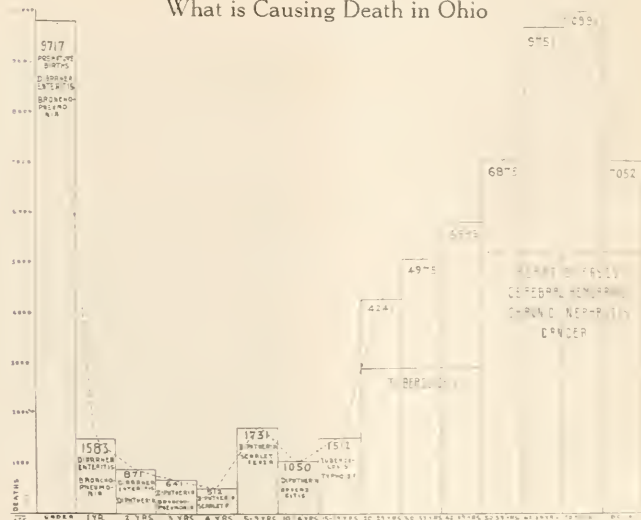

any means exhaustive, but by this very terminology of the newer health program we apprehend clearly that back of them all must lie, first, education of the individual in hygienic principles and, second, an intelligent voluntary response on the part of the individual to this education if our health conservation program for the future is ever to be made effective. In fact we may reasonably say that the health program of the future will be effective directly in proportion to the application of four fundamental factors each of which can only be successful by the active participation of the individual citizen. These are, first, personal assimilation of the simpler principles of personal and community hygiene; second, personal volition or a will to put this knowledge into effect; third, an increased degree of self-control by the average individual with a corresponding increased ability to regulate by the rule of reason and moderation the ancient instincts of man whether they relate to sex, food, drink, pugnacity, work or sloth, or such mental instincts as fear, hate and envy, and fourth, an increasing instinct to regulate individual hygiene by the dictates of altruistic promptings towards our fellow men, which last may sound sentimental but in reality is coldly scientific as well.

The goal is now clear. It is to establish the span of average existence upon the plane of the maximum aver-

age physiologic efficiency of the human body. Strictly speaking, up to the present time it has been only the very exceptional person who has lived a normal human life to its conclusion, for nearly all of us die prematurely. But now we know enough to change this; we know now that there is no such thing as an "inexorable law of mortality," we know that "public health is purchasable and within reasonable limitations each community can fix its own death rate." We know that the classic statement of Babbage: "There are few things less subject to fluctuation than the average duration of life of a multitude of individuals" is absolutely erroneous.

Obviously there is sufficient scientific knowledge extant, if intelligently and universally applied, to prolong the span of average human life by many years, and to make all these years much more abounding with the joy of living that accompanies top-notch physical condition than is the case with the average person today. A committee of the American Public Health Association has recently reported that whereas average American life expectancy is now probably in the neighborhood of fifty years there is no insurmountable obstacle in sight to increasing that average expectancy by at least twenty years in the next few generations. Surely this is a goal worthy of our best endeavors.

What is Causing Death in Ohio

Analysis of the 67,000 deaths of 1921 in Ohio has been made and graphically portrayed to show the greatest causes of death by age groups. This is Chart No. 3 of a series of charts issued by the Ohio Public Health Association for use on bulletin boards to give out vital facts pertaining to health conditions in the state. They are issued twice a month.

3. Annual Report of the Year 1921, by Sir George Newman, chief medical officer, British Ministry of Health, p. 27.

Infant Welfare in Saxony*

AMONG all dangers to which the human infant is exposed, none is so great as faulty nutrition. Sixty per cent of all infant mortality in Germany is caused by errors in nutrition. These are the observations of K. A. Lingner's excellent monograph on the organization of a National Center for the protection of infants and mothers in Hess in 1908, a monograph, which in connection with the Lingner Foundation, played an important part in the passing of the Saxon Welfare Law of May 30, 1918. But infants' welfare work was carried on in Saxony before 1918, not only in the larger but also in medium-sized cities and here and there in the country. There were scattered consultation stations, milk kitchens, and day nurseries created after the passing of the law, which caused a tremendous increase in female work. But what was lacking was the systematic handling of the problem by trained workers, and proper financial support. These necessary preliminaries were created by the law of 1918. Under the influence of the ideas and plans of Lingner, that were contained in the orders of February 4, 1919, the first emphasis of the newly founded welfare district stations was put upon the expansion of the public infants' welfare work, the fundamental idea of which was the furthering and securing of the natural feeding of the child. Mothers' information stations were systematically created, everywhere in great numbers. In 1920 there were 456; that is, ten times the number before the passing of the law. There are districts that as a matter of principle take charge of every mother and infant, and others that are content with those that come voluntarily. It is, of course, a question of the available trained forces as to whether it is possible to follow up every birth reported.

With the women's clinics it has not yet been possible to obtain complete reports. According to the report of 1920, which in the meantime may have been surpassed, in 62 districts all births were recorded through the local register. In 7 districts the district nurses were still forced to examine the list themselves. New-comers among infants and small children were in 4 districts reported by the office for the registry of inhabitants. In 16 districts the midwives were obliged to report all births to the welfare station at once.

After the report a visit by the district nurse is made to ascertain the physical and financial, as well as other conditions of mother and child. In case of need the district nurse immediately takes charge and makes use of the proper sources of help. In other cases she will go no further than to draw the mother's attention to the importance of natural feeding and of visiting the mothers' advice station. The issuance of nursing certificates for the obtaining of weekly assistance through the mothers' stations is a good means of getting the women accustomed regularly to visit the advice stations. Up to date the mothers' stations have made the most of this possibility. In 1920 the situation was such that in 55 districts the certificates were issued by the midwives, in 33 by the district nurses, in 10 by the doctor, in 3 by the sick fund office and in 1 by a woman's club. In 2 districts the certificates of the midwives had validity only when countersigned by the mothers' station. The midwives do not cooperate with all advice stations. In 39 districts cooperation is reported, and stress is laid upon the almost universally cordial relations with the midwives. As to the extent of the medical cooperation, the reports of the nursing districts for 1920 give no clear idea. In 68 districts the ad-

vice stations are, as they should be everywhere, under medical supervision. In all other districts medical aid is not always available, the cooperation being limited to occasional visits of inspection. The mothers' advice stations have been placed in the houses of ministers, cantors, teachers and doctors, in schools, hotels, and often in rented rooms in the welfare centers themselves, the furnishings being supplied by the municipalities, women's clubs and individuals. In 1920 the mothers' advice stations, covered on an average only infants to the end of the first year. Children up to two years were taken into the nursery in 31 stations, children from two to six years, in 27 stations and up to seven years in one station.¹

Advice to pregnant women is practiced in 36 stations, and very often a strong interest in improving home-nursing is observed. Home-nursing societies provide nurses for the protection of the mother, who in this manner is for the time being relieved of the worries of the household and family, and placed in a position to take the needed rest and care. The interest in this institution has grown mainly through the fact that the expense is borne by the sick insurance and weekly assistance fund.

1. These figures will have undergone changes to the advantage of small children in 1921. It embraced of all infants less than 50% in 4 stations, 30-40% in 11, 40-50% in 80, 50-60% in 19, 60-70% in 23, 70-80% in 14, 80-90% in 7, 90-100% in 3, and 100% in 9.

Japanese Scientists Visit America

A party of distinguished scientists now visiting the United States from Japan is visiting the chief laboratories and medical centers of the country under the auspices of the Rockefeller Foundation.

Work Against Venereal Disease in Rochester

By GEORGE W. GOLER, M.D., AND JOSEPH ROBY, M.D., THE HEALTH BUREAU, ROCHESTER, N. Y.

IN OCTOBER, 1914, we opened a consultation and clinic for infectious diseases in the Health Bureau; published the advertisement (Fig. 1), and distributed the signs (Fig. 2), phrasing the advertisement as it is published to cover all infectious diseases, so that the patients attending the clinic might not be stigmatized as venereals.

The health officer, deputy health officer, and Dr. Franklin Plumley, a volunteer worker, conducted the consultation and clinic for the first three years, after which period the consultation became a clearing house for the control and clearing of patients to the Baden Street Dispensary and the three hospital dispensaries. The State Department of Health gave the Wassermann tests, the deputy health officer the dark field examination, and the Health Bureau furnished arsphenamin and mercury in suspension for intramuscular injection. Inunctions were not used.

Situation and Furnishings

The consultation and clinic were in the Health Bureau, situated in the central part of the city. The general waiting room was the waiting room of the Health Office. The consultation and clinic were in a room 10x12. Table, desk, chairs, bowl, hot and cold water, small sterilizer, syringes for intramuscular injection were provided, as were cotton, alcohol, etc., and an intelligent nurse was in attendance, supplementing a talk on the disease. A booklet on syphilis and gonorrhea was given to each patient.

From small beginnings in two years the consultation grew until the waiting room, a space 12x30 was so crowded there was not room for patients to be seated. The hospital superintendents and representatives from the different hospital managements were then asked to visit us so

that they might see the need of venereal clinics in the hospitals and for serial Wassermann tests on all classes of entering patients at all times.

The Problem Involved

It is comparatively easy to get patients to come to a V.D. clinic. The problem is to hold them after they begin to come—to use force for the purpose without the appearance of force. We got the patients and we held them. The police power of the Public Health Law under Article xvi, Sec. 326-A, "Control of Careless and Dangerous Patients," might have been of little use but for the cooperation and enthusiastic support of the work given by City Court Judge (now county court judge) Gillette, and, later, down to and including to the present time, that of City Court Judge Kohlmetz, and through the whole period of time by Chief of Police Quigley. These judges and the police chief have thoroughly and enthusiastically supported us in the operation of this law. Recalcitrant patients are sent for by the police bureau and, when found, brought to bar by the police. The judges have uniformly committed such patients to us under the law.

What of the Patient

A summary of the work extending over a period of years shows that now and then a patient told a friend to come to the clinic and when the hospitals opened their clinics they referred their own patients to their own clinics; but it was by advertising in the newspaper, and by advertising alone, that a knowledge of this work was extended and patients came to the clinics.

When once a patient with syphilis was found, (and the operation of the clinic was chiefly against syphilis) what was done with him? A dark field examination or a Wasserman having shown the presence of syphilis, the patient was told of the dangers of the disease and induced easily to attend the clinic or, failing in this, was compelled to do so. All other members of the family and any known contacts were induced or compelled to submit to Wassermann tests, and those found positive had either to become patients of a physician who would report, or had to submit to the rules of the clinic. At the clinic courses of mer-

cury in suspension were given. Patients were sent to the Municipal Hospital for courses of arsphenamin. Wassermanns were taken at appropriate intervals. The patient was kept under control until he became both blood and spinal Wassermann negative, the final spinal Wassermann being one of the preliminaries for discharge.

Physicians were requested to report their private cases. Cards similar to the following were sent to them at stated intervals:

Rochester, N. Y.
This is to certify that, (name of patient) is still under my care.
(Signed) M.D.

Many of the physicians cooperated; two of the specialists objected until they found that the work of the bureau operated to keep their patients under control, for the public as well as the private patient usually received medical treatment just as long—or maybe a little longer—than active symptoms persisted. It was the consensus of opinion by five well known syphilographers, that not more than 5 per cent of even well-to-do private patients remain under treatment for a sufficient time to effect what we call a cure.

Time passed, the work grew until in 1919 it became impossible with three physicians and one nurse to care for the patients in the clinic, and at the municipal hospital to provide for the arsphenamin given these patients. Clinical work was, therefore, divided between the Baden Street Dispensary, the General, Homeopathic, and Highland hospital dispensary. This man-

Fig. 2.—Consultation made easy, the stigma removed, the clinic became the clearing house for venereal patients at legitimate institutions.

ner of doing the work has continued to the present day.

No work in recent years has more clearly proven the unpopularity and difficulty of reform in medicine, even after the value of our methods had been clearly shown. At first the hospitals could only with difficulty be induced to do routine Wassermanns, even among their ward and maternity patients. They rather preferred to remain in the dark concerning unknown cases of syphilis in their wards, even occasionally to open an abdomen for a suspected gastric ulcer, when a Wassermann test, together with the clinical signs would have shown the patient suffering from the gastric crises of tabes, than to take routine Wassermanns on their patients. But the hospitals finally did open free day and night clinics, and later followed them with pay clinics, one of them self-supporting.

The Health Bureau, having turned the clinical work over to the Baden Street Dispensary and the hospitals then became a consultation post where patients are received for advice, diagnosis and reference to a clinic. It also discharges the important function of following up the patient.

Since the clinic opened eight years ago there have been 1,726 patients; 41 have died; 436 have been referred to physicians or have removed to other cities, most of them under control by being referred to clinics in other cities; and 514 have disappeared, leaving 735 under active treatment or observation. More than a thousand patients are now reporting to the clinic, equally divided among dispensary and private patients of other physicians. The object of the clinic is not so much the cure of syphilis as the treatment of syphilis. Most patients report for treatment late. We hope to restore them to work and earning power, to protect the patient, his possible descendants, the family and state.

Methods Are Individual

In the clinics each case is a law unto itself. In a general way the following methods have been followed: Every sore is looked upon as suspicious. It is examined with the dark field, because we have found spirochaeta in sores that in the older days would have been passed by as abrasions or herpes or chancre. Chancroids are very rare. A Wassermann test is done on every patient. If we fail to find spirochaeta, the patient is told to come again and another search is made.

In active syphilis (primary or sec-

SYPHILIS

Is NOT, correctly speaking, a Venereal Disease. It may be contracted or communicated in other ways.

BEGINS as crack, fissure, abrasion, or ulcer at point of infection, often slow to heal.

Sure Diagnosis at this time by Microscope ONLY.

FOLLOWED in six weeks by rash, sore throat, fever, enlarged glands and malaise. It may finally attack every organ of the body, causing blindness, locomotor ataxia, paresis, etc.

DIAGNOSIS confirmed by Blood Examination.

TREATMENT by not less than Six Doses of "606" not more than six or seven days apart MAY SAVE years of terrible disease, perhaps YOUR LIFE.

If suffering from this disease, it is YOUR PATRIOTIC DUTY to take treatment AT ONCE. DELAY in TREATMENT makes it much more difficult to cure.

HEALTH BUREAU

Fig. 3.—In Rochester, he who runs may read, and thus secure the authentic information that is his best safeguard against disease and against charlatanism.

ondary stage) the treatment is more active than in the tertiary stage. The routine for the active cases, so far as there is any routine, is to give two injections a week with arsphenamin intravenously in doses of 0.1 gram to 30 pounds body weight and an intramuscular injection of mercury salicylate from 1 to 2 grains in oil. From six to eight or ten doses of arsphenamin and mercury are given in this way, a Wassermann test being made at each dose. Then the patient is given a rest of a month and another course of arsphenamin and mercury is given, the subsequent treatment depending upon the Wassermann test. Even if a negative Wassermann has been obtained, the patient is given about twenty-four to thirty doses of arsphenamin, extending over a year. After a negative Wassermann has been obtained two or three courses of mercury inunctions are administered, and, finally, a course of mercury by mouth.

The tertiary stage or congenital conditions are handled in the same

way, except that the treatments with arsphenamin are given once a week.

Our reasons for giving neo-arsphenamin are the sharp reactions that occasionally develop after the use of arsphenamin and the occasional difficulty of getting into a vein. We find that we can use the neo on the small veins of the wrist or back of the hand where we cannot use the arsphenamin. In this connection we have found very useful a suggestion of Dr. Wentworth of Rochester, in the use of the femoral vein. It is an easy vein to enter and is so large that thrombosis apparently never ensues. Our patients have been much less liable to unfavorable reaction if the solution is run slowly and if the patient sits up in a chair.

Finally, patients are never discharged. They must have a negative Wassermann of the spinal fluid before active treatment is discontinued. And after that they report at first once in six months, then once a year for blood Wassermanns.

Homeopathic Hospital; Highland Hospital.

INFECTIOUS DISEASE CLINIC

The public and physicians know that neglected infectious diseases exist. Most, but not all of these, are venereal diseases. Some are hereditary, some are acquired, many of them innocently. These diseases are commoner than physicians or public supposed. They were neglected until prior to the great war. They were not much talked about before the war. The Army found that these diseases prevented men from being "Fit to Fight."

The Public NOW KNOWS that these diseases make men unfit to Earn a Living; cause Blindness in Children, Peritonitis in Women; Organic and nervous diseases and insanity.

We are going to PREVENT these diseases. We are also going to TREAT THEM. For those already infected it will require LONG, CONTINUOUS TREATMENT to be made WELL.

BEWARE OF QUACKS and those who do not use the microscope, blood tests and other scientific means for diagnosis and treatment.

Both FREE and PAY CLINICS have been OPENED FOR THE DIAGNOSIS and TREATMENT of these DISEASES.

FREE—At THE HEALTH BUREAU, Mondays and Thursdays, 3 to 4 p. m. Mondays, 7 to 8 p. m.

FREE and PAY—At BADEN STREET DISPENSARY, Tuesdays and Fridays, 8:30 to 10 a. m. Tuesdays, 7:30 to 9 p. m.

FREE and PAY—At ROCHESTER GENERAL HOSPITAL, Tuesdays, 4 and 7 p. m. Thursdays, 1 p. m.

Fig. 4.—As the work grew and proved its efficacy other agencies were induced to provide the necessary facilities to handle the referred cases, the Health Bureau, serving as a consultation clinic to diagnose conditions and assign patients for treatments by other agencies.

National Organization and Child Health Work*

By DONALD B. ARMSTRONG, M.D., EXECUTIVE OFFICER, NATIONAL HEALTH COUNCIL, NEW YORK CITY.

IT IS recognized by all that the national movements become effective through the local contacts. The local organizations are the feet upon which the national movements stand. The local field is the point of precipitation for the program, where a more or less ethereal aspiration is translated into a concrete body of service.

There are, of course, certain general ways in which all national health movements strive to serve community efforts. Chief among these are the following:

(1) The establishment of scientific standards, such as the work being done by the National Child Health Council Committees on food and nutrition, standard weights and heights for school children, etc.

(2) The development of general basic information, such as the statistical municipal mortality summaries of the American Child Hygiene Association.

(3) The development, from special research, of ammunition for use in local programs, such as the data being acquired from such demonstrations as the Framingham tuberculosis work under the auspices of the National Tuberculosis Association, and the Mansfield Child Health Demonstration under the auspices of the National Child Health Council.

(4) The training and stimulation of personnel, as carried out by the National Tuberculosis Association semi-annual institutes.

(5) The development of such special devices, as the health clown or the health fairy, as initiated by the Child Health Organization of America.

It seems probable that one of the most useful services which the National organizations have performed for local agencies in the last few years is the elimination of confusion and duplication in organization on a national scale. The child health field in particular is marked by real progress in recent years. We have now the National Child Health Council, an organization that endeavors to coordinate the educational, scientific and field interests of the chief movements interested in the promotion of health among children. Its membership includes the following organizations:

The American Child Hygiene Association, the American Red Cross, the Child Health Organization of America, the National Organization for Public Health Nursing, the National Tuberculosis Association, and the National Child Labor Committee.

More recently, a successful movement has been carried out still further to coordinate these organizations. This involves the actual amalgamation of the American Child Hygiene Association and the Child Health Organization of America—the two organizations principally interested in child health. Consideration is also being given to the relation of such a merged group to the vitally important child health program of the National Tuberculosis Association through the Modern Health Crusade, and it is hoped that local organizations may before long reap the benefit of a closer integration of effort in all of these child health fields.

It may seem from this point of view that the National Child Health Council is rapidly working itself out of a job, so to speak. However, even though it will have accomplished noteworthy and, indeed, unique results, it will still have definite work to do, or to "bequeath" to other agencies, through its important advisory committees, in connection with the administration of the Mansfield Demonstration, etc. Further, the National Child Health Council bears an important operating relationship to the Child Health Committee of the Commonwealth Fund—a committee recently appointed to administer the child health demonstrations to be carried out with the financial support of that Fund in the Mississippi Valley, in the west and south. There is approximately two hundred and fifty thousand dollars a year available for an effectively coordinated child health program in typical American communities still to be selected. From this experience, supplementing as it will the Mansfield and other studies, there should be derived a tremendous amount of supporting and guiding data for the effective pursuit of disease prevention and health promotion among children in all parts of the land.

Nearly everyone is familiar with the specific services which the existing national child health agencies are

offering to state and local groups. It may, however, be worth while to review a few of the more important of these contributions.

(1) From the former American Child Hygiene Association we have the publication *Mother and Child*, which fills an important niche in the field of health. Then, too, there are the annual statistical reports of this organization and the lecture and consulting services offered by the staff.

(2) Through the American Red Cross, particularly through its Junior Division, assistance can be secured for the establishment of the Junior Red Cross in the schools, aiming as it does at the promotion of health habits, of civic responsibility, and at foundation building in community welfare.

(3) From the former Child Health Organization of America, interested as that organization is, particularly in the school child, have come for use in all of our communities not only literature, but unique educational devices, including the health clown, the health fairy, the health theatre, etc. All who have taken children to the circus in the last few years, and have heard the consecutive exclamations from rows of children of "Here comes Cho Cho" as the circus clown makes his first round of the sawdust ring, have realized the effectiveness of this method of health education.

(4) From the National Organization for Public Health Nursing have come standards of nursing, methods of training and securing personnel, methods for teaching all phases of child health nursing work, including prenatal, infant, pre-school, school and early industrial interests.

(5) From the National Tuberculosis Association, a most vital contribution, namely, the financial resources for the development of the field service program as derived from the Christmas seal sale, for a major portion of the practical child health work, as established in our American communities. In addition, there is the extensive organization reaching millions of children in our schools known as the Health Crusade, as well as the standards for diagnosis and treatment of tuberculosis among children as developed by the Framingham Demonstration committees.

(6) Finally, from the National Child Labor Committee, we have the publication known as the *American*

*Address delivered before Nursing and Child Health Sections of the Maine Public Health Association, Lewiston, Me., August, 1922.

Child, dealing primarily with health and welfare interests of the child entering industry.

While this exhausts the list of the organizations holding a membership in the National Child Health Council, there are other organizations—associates of the National Child Health Council in the membership of the National Health Council—that deal with equal directness and significance with many important phases of child health work. Among these is the American Social Hygiene Association. This organization, through its work with health authorities in the prevention of venereal disease, brings to bear a tremendous influence towards the prevention of stillbirths, the elimination of preventable blindness, etc. Perhaps more important in its program is the general work for sex instruction and the promotion of home hygiene.

Of equal importance from certain angles is the National Committee for Mental Hygiene. The education and direction and adjustment of the abnormal child in school, at work, at play and everywhere, has an important relation not only to mental health, but to physical health and to

community hygiene as well. The resources of this organization, as well as those of all the others whose contributions to child health have been briefly and incompletely touched upon, are available to meet the needs of local communities everywhere.

It is recognized by all that in the promotion of health, education is the important thing. It is also becoming increasingly evident that the child is the only one that can be hopefully approached with the object of altering habits. The plastic period of childhood, in contrast to the static condition of the adult, possesses unabsorbed instinct energy. He alone is willing to practice health for health's sake.

Then it is also realized that the greatest strides in the past, in the work for preventive medicine, have been made in the fields of tuberculosis and child health. We seem justified in assuming that in the child health field lies one of our greatest hopes for the future. Certainly hygienic conditions among children constitute one of the keenest indices of community welfare. The work for child conservation aims at the protection of the nation's greatest asset.

these two rates continue unchanged they will coincide in 1926.

1922-1911	30.0

ity of the population of the U. S. registration area. (Figure 2.)

The downward tendency of mortality of insured children has been twice that among the children in the general population of the registration area.

Life Insurance Service

IN "What You Did in 1922," a statement of the public service of the managers of the Metropolitan Life Insurance Company, it is stated that the visiting nurse service of the company cared for 426,926 persons in 1922, which is a gain of 98,759 over the 328,167 cases reported in 1921. The distribution of health literature amounted to 33,322,161 pieces, a gain of 7,966,859 over the high mark of 1921.

The health record of 1922 was extraordinarily good in the reduction of deaths from typhoid fever (now one-fourth of the 1911 rate); from tuberculosis (now one-half of the 1911 rate); and from the communicable diseases of children (now one-half of the 1911 rate). The protective health work of the managers has helped in securing this reduction which means that approximately 52,000 persons were kept from dying in 1922 who would have died had the rates of 1911 prevailed.

Another publication of the same Company, "Lengthening Life Through Insurance Health Work," shows that there has been a saving of 15,000 lives in 1922 by the decline of the tuberculosis death rate since 1911. (Figure 1.) The downward tendency

of the death rate for all forms of tuberculosis among Metropolitan Industrial policy-holders is twice as great as in the population of the U. S. registration area. Should the decline of

Inspection of Soft Drink Establishments

By IRA V. HISCOCK, ASSISTANT PROFESSOR OF PUBLIC HEALTH, YALE SCHOOL OF MEDICINE, AND ANNA I. VAN SAUN, DIRECTOR, BUREAU OF LABORATORIES, DEPARTMENT OF HEALTH, NEW HAVEN, CONN.

THE most casual observer cannot fail to recognize the phenomenal increase in the consumption of soft drinks throughout this country during the past five years. Recent estimates indicate¹ that the equivalent of over four billion pints of bottled sodas are now consumed annually in addition to the enormous amount of soft drinks at approximately one hundred thousand soda fountains in the United States. This rapid development of a business which reaches a large percentage of the people of both urban and rural districts has created a public health problem of considerable importance. For many of these beverages are mixed and bottled by untrained individuals in surroundings which are insanitary, while others are served in dirty containers to the unsuspecting public. Skinner has well said that the provisions of the Federal Food and Drugs Act should be applied to such products, and that activities under the federal act should be supplemented by adequate state and municipal control.

In one of our largest cities where considerable attention is given to this problem, there were, before the passage of the Volstead Law, seventy soft drink manufacturing establishments. Today there are 130.² Inspections and laboratory examinations here as in other cities, indicate that many of the soft drink preparations are produced under conditions which render them unsafe for human consumption. As many as forty of the establishments are reported to be under orders to make necessary changes to bring them up to standard, or to discontinue business.

Small communities are concerned fully as much as large ones. A survey of bottling works and soda fountains in a small city made in 1920 by one of the authors revealed conditions surprising even to a health inspector. While two of the large plants were in excellent condition, careless washing of bottles by unskilled workers in dark, poorly constructed establishments (shed-like structures in rear yards in two instances) frequently represented the first stage of the

process in other cases. The syrups, although received in apparently satisfactory condition, were often mixed in rooms unscreened and otherwise unprotected from contamination and later passed through cheese cloth of questionable cleanliness on the way to the bottles. Although the filled bottles were eventually passed over an electric light for the detection of visible dirt, this procedure was not sufficiently supervised, as demonstrated by the fact that many samples containing flies and other visible sediment (not the precipitates sometimes found in bottle sodas) were picked up in the open market and brought to the laboratory by citizens and inspectors. Such complaints were rarely heard concerning the products of the better regulated establishments. Our experience in other cities leads to the conclusion that the above experience may be duplicated elsewhere.

The soda fountains of the same city presented equally undesirable conditions. Of thirty-seven fountains, eleven were filthy, nineteen others had no hot water and only seven were satisfactory. In some instances there was no indication that soap was used in washing and the wash water was usually very dirty and rarely changed. In most of the eleven cases above mentioned, the hands of the men as well as the utensils, were extremely dirty. Only two of the 37 fountains used individual drinking cups entirely, while a few others used them upon request. Several fountains operated milk pumps which, according to the testimony of the workers, were not cleaned every day, and the intervals were doubtless much longer in many cases. Definite improvement resulted in the bottling works and soda fountains with the institution of frequent inspections and regular laboratory analyses.

Active Control Necessary

The recent experience of inspectors of the State Board of Health of Alabama is also suggestive of the need for active control of this problem.³ Inspection was made of the soda fountains of a representative city of the state and cultures were taken from various drinking glasses ready to be used. Forty per cent of the glasses

examined were actually infected with germs commonly found in the nose and throat, while an additional 20 per cent were dirty or infected with germs of putrefying matter. Only 40 per cent of the glasses were considered safe to use. Less than 7 per cent were sterile and these glasses were found in a place which employed a boy during rush hours for washing glasses in hot water and soap.

The following extract from a recent health bulletin of another state is also interesting in this connection. "While there is some excuse for the small, unincorporated town which has no health officer, it is surprising to find in two of the largest communities conditions such as were observed at presumably first-class soda fountains. In one place, the cherry not consumed by the purchaser was thriftily transferred to the next drink ordered. In another place, this was done with the ice, which was put into the next glass without the formality of being washed."

Inasmuch as there are so many popular drinking fountains which do not properly sterilize or even clean the glasses and spoons, and inasmuch as this is an easy and dangerous manner of spreading disease, it seems that measures should be taken to improve the situation. While many of the sterilizers installed in soda fountains in various parts of the country in 1917 and 1918 may have demonstrated their usefulness, others merely gave a false idea of protection to the public for they were either not used at all except to adorn the back of the fountain or else were operated at too low a temperature for sterilization and hence were valueless.

One naturally expects the large cities to be leaders in health supervision of this kind. A few of the city and state health bulletins—notably New York, Chicago, New Haven and the states of Alabama, California and Connecticut among others—have already directed attention to the importance of the problem. It is interesting to note the findings of the Committee on Municipal Health Department Practice of the American Public Health Association.⁴ Of the eighty-three cities of one hundred thousand population and over surveyed, a little over half (forty-nine) had, in 1920, special regulations for

3. "Dirty Glasses Are Germ Carriers," by C. A. Abele, *The Soda Fountain*, July, 1922.

the sterilization of utensils at soda fountains. Some of these regulations were of state rather than city origin, and others were entirely inadequate. The report states that "apparently there is much to be desired in many of our cities in enforcement of regulations requiring proper cleansing and sterilization of eating utensils." Lack of supervision of bottling works was even more striking. In many cities new regulations are needed, whereas in others, enforcement of existing codes would bring the desired results.

As one basis for formulating practical measures of supervision it may be worth while to recall briefly the experience of a few cities which have taken the lead in this work. In 1916, the department of health of New York City studied methods of dishwashing and Mannheimer and Ybanez⁴ concluded that boiling water is necessary for sterilization. Dr. Jane L. Berry of the New York laboratories found that a saturated solution of chlorid of lime gives practically instantaneous results in sterilization of glasses, and her work has been confirmed in the New Haven Laboratory.⁵ It is recognized, however, that a hypochlorite solution, to be effective, should be made up freshly each day, with considerable care. Consequently, as a practical measure, we do not feel inclined to recommend this procedure for routine disinfection purposes.

In order to prepare rules for the guidance of those dispensing drinks without inflicting hardships on the owners of establishments, the New Haven health department undertook research investigations on this subject in 1919. These studies showed the need of enforcement of the existing ordinance and gave interesting and instructive information regarding the solubility of soap powders and cleaning solutions, as well as their possible bactericidal qualities. The laboratory was enabled to suggest simple methods of washing utensils⁶ which could be used by any firm maintaining a soda fountain, ice cream parlor, or lunchroom. Personnel was found to be a determining factor in the proper upkeep of these establishments. Conditions while by no means ideal are much better today, partly as a result of the investigation and partly because of the increased demand

for soft drinks which creates much competition and makes for the employment of a better class of workers. Paper cups are very generally employed in many of the better class places. Checking up of the less desirable places is much retarded because of distances and the lack of adequate automobile service for the inspectors. Our experience with sterilizers as used in places maintaining soda fountains would indicate that a definition of sterilization is as much a necessary part of any ordinance as would be an indication of the proper method for washing glassware. Sterilization should really read disinfection by heat or other means.

Public Demand for Cleanliness

In order to improve the general quality of beverages dispensed at different stands and soda fountains, and

to protect the public from the dangers that may result from improperly cleaned containers and careless attendants, greater supervision should be exercised directly by the health department. The dispenser may be stimulated through an appeal to the commercial side of his work but the general public must also be educated to the desirability of cleanliness in places in which it consumes food and drink. However, while sanitary conditions should determine patronage, location and the personality of the dispenser both play important rôles. As Mr. Able, director of inspection of the Alabama state department of health has well said: "The problem today exists in the small corner fountains on the skirts of the business center or in the outlying sections of the community, or in the rural founts."

First of all there is necessity for

7. loc. cit.

an ordinance to meet the needs of the individual community governing the operation of soft drink establishments and soda fountains and requiring permits for their operation. These permits should not be issued until inspection has shown that the location, construction, and equipment of the buildings meet the approval of the health department. Furthermore, provision should be made to insure the right type of personnel and to quickly eliminate anyone afflicted with communicable disease. Sections 37-47 of the sanitary code of the department of health, of Yonkers, N. Y., governing the manufacture and sale of ice cream and soft drinks and the regulations of the Alabama state board of health admirably cover this situation.

Second, special regulations should be promulgated and enforced requiring the disinfection of utensils used in serving drinks to the public. (a) In the case of bottling works, provision should be made for the washing of bottles in alkali solutions of proper

strength (3 to 6 per cent) at temperatures of about 120° F., followed by thorough rinsing in hot water. (b) In the case of glasses and spoons at soda fountains, efficient washing in hot, thoroughly dissolved soap or other alkaline solution frequently changed should be practical (jars of soap jelly might be kept on hand for the purpose) after which all utensils should be rinsed with clean hot water. Individual paper cups, carefully kept from possible contamination, are highly desirable.

Third, regulations should be enforced for the protection of all drinks to be consumed by the public from contamination with disease germs by means of unclean vessels in which they are prepared, stored, or served, and from flies, gnats, or similar insects, and gross particles of foreign matter or dust.

Fourth, medical examinations for the detection of tuberculosis, typhoid carriers, venereal diseases and skin eruptions should be made at intervals,

of all persons engaged in the preparation or serving of soft drinks to the public.

Fifth, there should be inaugurated regular inspections with collection of laboratory samples, and scoring of soda fountains and other soft drink establishments. Such inspections require high grade individuals rather than mere political employees, as they must be carefully performed. At times, as for example in New York in 1920 when influenza was prevalent, it may be advisable to institute special inspection service. Particular attention was then given to restaurants, lunch rooms, drug stores, and other establishments where soda water and beverages were dispensed. Although care was exercised not to issue permits until proper washing facilities were installed, it was necessary in fifty-six instances to serve summons on store-keepers or stand-keepers who failed properly to cleanse food and drinking utensils after use.⁸

Score cards have demonstrated their value to food inspectors and apply equally well to this service. A sample score card for bottling works which has already proved its usefulness is reproduced through the courtesy of the Richmond health department. In addition, a somewhat different type of score card for soda fountains is presented, through the kindness of Mr. Abele, who writes as follows: "The demerit schedule of scoring has been adopted by this bureau. We assume that all establishments have a perfect score before we inspect them. Our inspectors then point out deficiencies, and demerit the establishment accordingly. When the score is complete, the proprietor has his deficiencies especially called to his attention by his demerits. The inspector has had to place only a few figures on the schedule, and I find it of considerable advantage in the compilation of reports or detailed studies of conditions. Whenever the regulations are amended, further deficiencies can be charged against the total scores without altering the whole schedule."

8. Monthly Bulletin, Department of Health of New York, September, 1921.

The minimum unit for a full-time county health department in California consists of a full-time physician as health officer, public health nurse, sanitary inspector, and office clerk, each of whom must devote full time to the duties of his office. The minimum annual appropriation is \$10,000. Such units have recently been organized in Monterey, Orange, San Joaquin, and San Luis Obispo counties.

Public Health Progress in Czechoslovakia in 1922

By HYNEK PELC, M.D., C.P.H., SPECIAL CORRESPONDENT OF THE NATION'S HEALTH, PRAGUE, CZECHOSLOVAKIA.

THE Czechoslovak Republic has recently completed the fourth year of its independent existence. It seems worth our while to glance briefly at the last of these four years and observe how much has been achieved in the way of health conservation in this nation counts a population of thirteen and a half millions.

Three important laws bearing on public health were enacted during 1922. By the first of these, the state took over the salaries of local health officers so that the Ministry of Health will have its direct representatives in localities from five to six thousand inhabitants and upward. The local health officers will be part time appointees and the salary will be larger in poorer districts than in those where the physician will be able to make his living from private practice. It is understood that this is a provisional arrangement and that it is only on account of the strictest economy which must be enforced in every branch of public service that the public health administration must content itself with such a part-time service.

A venereal diseases law was enacted, making the treatment of venereal diseases obligatory and providing free treatment for those who are unable to pay for it. The "regulation" of prostitution was abolished and state control of the treatment introduced for persons who interrupt their treatment before complete cure. Thirdly, a law restricting the sale of alcoholic beverages to minors was put into force, which provides that no alcoholic beverages may be sold to persons under eighteen years of age.

The Ministry of Health augmented its budget from 149 millions to 207 millions in spite of the deflation policy of the government.

Two important studies were completed in the Ministry in the Division for Study and Reform of Health Activities. A complete tuberculosis survey of the state was published with an analysis of present institutions, an analysis of statistics and specific recommendations. A similar study was worked out for venereal diseases and is to be published soon; and a study of infant mortality is being prepared. A public health survey of Greater Prague was also issued.

The Ministry is developing a division of public health education. Every

The last four years in Czechoslovakia have seen the creation of a complete health organization, the successful enforcement of far-reaching statutory regulation, the institution of important research, and demonstrations looking toward the development of administrative technique.

Chairs of social medicine have been established in the schools and opportunities opened for scholarships in public health, and governmental interest is at play on far-reaching measures of insurance against invalidity and the infirmities of old age.

opportunity in the course of public life is seized by the Ministry in order to bring before the general public the idea of improving the health of the people.

A demonstration in rural hygiene was started in Kvasice to develop the technic of health administration in rural communities.

In the way of public institutions, a state school of dentistry was opened in Prague with a one-year post-graduate course for doctors of medicine. In the same city a radiological institute was equipped and given 3.2 gr. of radium which makes it the second largest institution of this kind on the continent. The number of beds for tuberculous children was increased by one hundred by a new sanatorium opened at Sumperk. The actual construction of the state Institute of Hygiene with a school of hygiene was started with the financial assistance of the Rockefeller Foundation.

Medical faculties in Brno and Bratislava were almost completed so that they will help the Prague medical faculty to master the influx of foreign students coming to Czechoslovakia for their medical education. The medical faculty of Brno created a chair of social medicine which is the first chair of the kind in the Czechoslovak republic. A public health course for physicians has been initiated.

The organization of health centers was continued and a number of tuberculosis dispensaries created. The Ministry of Health has taken over the twenty-one child health stations which

were created by the American Red Cross in all county cities and included them in the scheme of health centers.

A simplification of the work in the field of child welfare was brought about by the coalescence of two important child welfare organizations. A survey of child welfare work was made in the province of Moravia and the results shown at the child welfare exhibit in Brno.

The National Council of Social Hygiene, which is analogous to the American National Health Council, has framed its policy and become an effective organization for the coordination of the social and health work of the country.

The general congress of sickness insurance associations adopted a resolution in which the development of a health program by the insurance bodies was urged. The present government included in its program for the next year the organization of a system of compulsory old age and invalidity insurance.

An active committee on social medicine was developed by the young generation of the Czechoslovak Association of Physicians. A congress of social medicine was organized by some of its members in Carpathian Russia.

In the course of the year 1922 all foreign missions working in Czechoslovakia left the country. Mr. A. C. Ringland, representing the American Relief Administration, left early in the spring; Dr. H. O. Eversole turned over the child health centers erected by the American Red Cross to the Ministry of Health in the summer; and the English mission of Lady Muriel Paget withdrew in the first months of the year. The representative of the Rockefeller Foundation, Professor S. M. Gunn, transferred his residence to Paris.

This may be considered as a sign that Czechoslovakia has already returned to its pre-war vigor and the years' record seems to indicate that the development of the public health campaign will proceed in this country with increasing vigor as time passes with increasing enthusiasm as time passes on.

The Maternity Center Association of New York has offered a prize of one hundred dollars for the best scenario for a film designed to show the benefits of prenatal care.

Walls and Wings—The Spirit of Health Education

By GRACE T. HALLOCK, AMERICAN CHILD HEALTH ASSOCIATION, NEW YORK CITY.

THE wise men of Gotham once did several foolish things to keep the king from cutting off their noses. The silliest thing they thought of doing was to build a stone wall about a field to keep in a skylark.

In the past we have tried to build a stone wall about the health of our school children by teaching them only the dull facts of physiology and hygiene. We forgot, or else we didn't know, that stone walls cannot enclose the skylark mind of a child.

The field of health must be made attractive to the child before he will make it his abiding place. It must be stocked with food for his thought, wing space for his fancy, and a testing ground for the practice of what he knows.

Knowledge, imagination, practice—they are the three essentials of health education. Knowledge furnishes the child with information to satisfy his eternal questions. Imagination makes the knowledge attractive. Practice gives him a chance to use it for the formation of the good health habits.

One day about five years ago, while we were working on the outside of the field of health, a little boy passed by. He was inquisitive, as all little boys should be.

He stood awhile watching us pile long lists of the bones of the body on top of minute descriptions of the circulatory and nervous systems. Then he shifted to the other foot and said: "What are you doing that for?"

We replied: "Why this is a fine field, full of the sweet ripe fruit of health and the blue flowers of happiness. We saw a sturdy, rosy-cheeked boy in there the other day, and we all thought that if we could only keep him there what a fine man he would grow up to be. So we're building this wall to hold him in."

The little boy grinned. He was rather pale and thin but he had a smile—Oh my!

We were very busy, so we turned our backs on him then, but he didn't go away. He hung around throwing pebbles at the wall and scuffing his feet in the dust as all boys do in idle moments.

At last we finished the wall. It was high and strong. We couldn't find a crack in it anywhere. Historical scenes were set in niches around the inside to make it interesting. The lit-

tle circus boy was there who died because the gold paint hadn't been washed off before he went to bed. The Black Hole of Calcutta was there with all the people in it gasping for breath. If anything could keep a child in the field of health, we thought that wall would surely do it. No fact about the body had been left out. It was all very reasonable and sound.

We turned to ask the little boy what he thought of it, and lo! we saw a fluttering about his shoulders. He was grinning harder than ever.

"It's a fine wall all right," he said, coming a little closer, "and I know

Wide World Photos
School girls nowadays learn that health habits are more potent beautifiers than paint and powder.

what it's like from the inside, too. I watched you put up the Black Hole of Calcutta before I flew out."

"Flew out?" we gasped. "Why, are you the little boy we built the wall around?"

"I certainly am," he said. "Now, that Calcutta scene started out fine with a cave. I thought I'd stay awhile if you were going to make it interesting like that. I thought it might turn out to be a secret treasure cave, and then when it came to be what it is, it sort of scared me. I had a feeling in my chest as if I couldn't breathe, and that was funny because the 'breathing' part of the wall said that scene meant we need fresh air, and I was getting it all right. Well, after awhile I got sort of tired of staying in there anyway, so I just flew out."

"Flew out?" we repeated again.

"Why sure, don't you see my wings?" he asked. "All of us children have wings, only we don't go around showing them all the time. Most of us only use 'em when we have to get away from walls like this. It's funny; grown-ups don't seem to like wings," he added sadly. "Whenever we use them we get scolded. It's probably because of the walls."

One of us looked very thoughtful and then asked the little boy: "What would you advise us to do to keep you children from flying away from the field of health. You do, you know. Just look at yourself, your legs are skinny and your face is white. You couldn't win a race if you tried. And yet in there you were quite round and rosy."

We were all rather aghast at this turn in the conversation. Who ever heard of a grown-up asking a child for advice?

"I'll tell you," said the little boy sitting down on one of the long words that we couldn't fit into the wall. He turned to the one who had asked the question: "Suppose you were a little boy and someone gave you a set of blocks for Christmas. And when you'd taken the cover off the box you found that all the blocks had been glued together! You could set them up and learn all the A, B, C's on one side, and the cats and rats and ducks on the other, and the mother goose rhymes on the ends; but you couldn't make giants' castles with them or treasure caves or factories or churches with tall steeples. Or suppose you were a little girl like my sister and your mother gave you a doll's house for your birthday. But when you peeped inside you found that all the rugs had been glued to the floor and the curtains nailed to the windows and the chairs and tables and beds screwed to the floor. Suppose, even, that the dolls had their clothes sewed on and you couldn't undress them for bed or wash their petticoats!

"That's what you grown-ups do when you put the things we should know in walls. We like to know things, but it isn't any fun knowing, if you can't play with what you know or make things with it. That's where our wings come in. They are called imagination. They help us play and work with the things we know. Then pretty soon we do what we know we should without thinking."

Campbell Studios
The "Jolly Jester" of the American Child Health Association knows that children have wings.

"Knowledge, imagination, practice," murmured the one who had asked the little boy for advice.

"Now that field there," went on the boy jerking his thumb over his shoulder, "Why don't you tear down the wall and scatter the facts all over it? Put some of 'em down rabbit holes, and hide some in the trees. We could make a game of hunting for them ourselves. You might even hang a few from the stars so we could try our wings.

"But don't think, please, that we'll stay in that field because you say it will make us healthy and happy, or because you put a wall around it. Puff! What are health and happiness to us? Can we build castles out of happiness or make a game of

health? When you show us how to do that, we'll stay in your field forever. As for walls! What are walls to wings?" crowed he, as he flew far away into the blue sky.

We looked at each other, and then some of us said, "he's right."

That was in the spring of 1918 when the Child Health Organization of America (now incorporated in the American Child Health Association) was founded. Since then, the play spirit has infused new life into our old conception of health education. The game of health, with rules like any other game, is being played all over the world. "Judge Scales" presides on weighing day in thousands of schools and tells the children whether or not they are playing the game.

Imagination has given wings to the teaching of positive joyous health. And this movement of making health attractive through an imaginative appeal is not a mere flash in the pan, depending for its success on exceptional teachers here and there. It is not a monarchy whose only guarantee of good government depends upon the personality of a king. Rather, it is a world democracy founded on the principle that all children are created with the wings of imagination, and the right to have those wings used for the furtherance of sound bodies and happy minds.

Health Work in Colorado Expanding

Otero is the first county in Colorado to have voted the support of three public health nurses. This does

not include the two school nurses employed by School Boards in the towns of Rocky Ford and La Junta, which makes a total of five nurses in the county whose salaries are paid by public funds and provides one nurse for every four thousand persons.

A few farsighted persons believe that a project providing for three public health nurses supported by taxation could be carried on, but the general opinion was that during these days of high taxation support for one nurse was all that could be expected.

The Field Secretary of the Colorado Tuberculosis Association realized the tremendous need of disease prevention and care of the sick in this pioneer field, where there is a large floating and Mexican population and arranged for a public meeting with the county commissioners, which was attended by members of the Lions, Rotary, Commercial and Federated Women's clubs. Some of the heaviest tax-payers and most prominent citizens made stirring talks in favor of three nurses and convinced the commissioners that if the people were willing to tax themselves for better health, it was up to the county to carry out the people's wishes. The commissioners therefore voted \$54,000 to pay the salaries for three public health nurses.

This county has led the way in Colorado. There are five other counties where the public health nursing service has been taken over by county taxation. And wherever nursing service has been instituted other services have expanded accordingly.

Tuberculous Children Play Outdoors in Winter

At the left tuberculous children at the "Seaside," Niantic, Conn., enjoy skating and at the same time gain strength for their battle for health. At the right is evidence that the bench in winter is no less attractive to these children than it is in summer to the less hardy adult.

A Comparison of Methods of Street Cleaning

CITIES in the United States containing enough paved streets to produce a problem in street cleaning number more than seven hundred fifty. Many of these cities have been in the past, and far too many are at present, satisfied with methods that have left much to be desired regarding cost, convenience, and sanitation.

Before the recent war the greatest advances in this problem were made in England and Germany. Quite recently American cities have been giving much needed attention to the study of street cleaning. We have now apparently reached the point where methods in the United States may be held up as examples to the uninformed, according to George C. Dodge, author of a pamphlet entitled "What is the Eventual Street Cleaning Method."

The street cleaning methods of today are hand-patrol, sprinkling wagon, and horse-drawn sweepers, squeegee, flushing, motor driven combination machines that spray the street enough to settle the dust and sweep it and collect the sweepings, and suction or vacuum machines. It may be that time will wear out all but one of these methods and the system that stands this test of time will then be the "standard eventual major method."

Mr. Dodge's comparison of the advantages and disadvantages of various methods is made with a view to determining which of the systems have merits that may enable them to withstand the process of elimination that may eventually determine a standard method.

The hand patrol system has one feature that is not duplicated in any other system; a feature that will insure its use in some form or other in spite of competition. Its real merit lies in the fact that much refuse is removed from the street as soon as it is placed there. Horse droppings are removed almost constantly and the advantage of such prompt removal will insure the continued use of a patrol system though it is one of the most costly methods in use. It is reasonable to expect, however, that in time the "hand" will be removed and the push cart and broom will be replaced by a motorcycle type of machine that will dart in and out of traffic and pick up refuse quickly and economically. Another possibility is that a hand propelled machine may be devised that will increase the patrol-

ling capacity of the sweeper. "It may be to the pavement what the carpet-sweeper is to the home." But proposals that have been made thus far in this direction have been impracticable, and if one is finally evolved it will have to be different in fundamental idea from those already suggested.

There are several objections to the hand patrol system as it is now practiced. The first of these is equally applicable to all systems as practiced in the majority of cities. The defect referred to is the practice of employing old men, cast-offs, and in general the most inefficient type of labor that can be imagined. "It seems that every man to whom a city administration is obligated and who cannot be used elsewhere is placed in the street cleaning department."

Without making any brief for militarism it would seem that a department manned by first class personnel and subject to the discipline, organization, and routine of a police department would make for greater efficiency in a street cleaning department.

"Titles and rank to which a private might be promoted, with rewards for distinct service, strict discipline, and thorough and complete organization would be of immense help."

Another objection to the patrol system is that the refuse is often placed in cans, some times without covers, and these cans are then al-

lowed to remain on the curb for hours before they are removed by a collecting wagon. This difficulty can be partially removed by so timing collections that full cans will remain on the curb but a short time. An even better solution of the difficulty would be the construction of openings in the sidewalk with hinged covers into which the cans could be placed. The collecting wagon could then remove these and leave empty ones in their place.

The greatest objection to the hand patrol system, however, is its cost. Reports that it is the cheapest system are erroneous. It is in fact one of the most expensive if it really cleans the streets. The truth of the matter is that it cleans only that part of the street on which droppings or other refuse is found. The number of square yards allotted to a patrolman varies greatly. One city reports from 2,160 to 15,600; another 7,000 to 14,600; another 8,000. At the end of a day when a patrolman has covered such a territory he has not cleaned it; he has swept but a small portion of it. If the entire surface of a city's streets were really cleaned by a hand patrol system the expense would be terrific.

Commercially Clean Streets

This brings up the question of what is desired in a "commercially" clean street. Is the pavement to be left as clean as a well cleaned floor? The kitchen floor is swept to remove the coarse material and then mopped to

A style of patrolman's cart in which the dust pan can be raised over the can and contents dumped.

A horse-drawn squeegee.

remove the dust. A combination machine followed by a flusher or squeegee would provide similar technic for the street. Few would care to say just what is meant by a "clean" street. Local conditions are all important in a consideration of this matter but most cities would be willing to have their thoroughfares a little cleaner than they are today if this could be accomplished without an undue increase in expense.

In cleaning streets with a horse-drawn sweeper, a sprinkling wagon usually proceeds the sweeper and lays the dust. Sometimes a small tank is used on the sweeper which sprays water ahead of the broom. After the dust is laid the sweepers, which have a broom set diagonally with the forward end toward the center of the pavement, start in the center of the street and each trip works the furrows of dirt nearer the gutter. From this wind-row the refuse is either shoveled directly into collecting wagons or collected after first being shoveled into small piles about every thirty feet. The former method is very inefficient unless the collecting wagon follows the sweeper without any great loss of time. "It requires the services of three to five pieces of apparatus, as many drivers, sufficient number of horses to handle the apparatus, and a hand collecting gang of not less than two men under the best circumstances. A gang, such as outlined, should cover from 6,000 to 11,000 square yards per hour."

The sprinkling wagon, delivering water by gravity, has a greater rate of flow when it is full than it does

when nearly empty. Aside from this it commonly delivers too much water to the pavement and converts the dust into mud. The rotary broom then grinds this grit into the pavement to the detriment of the latter. The coarse matter is carried to the gutter but when the street dries the dust is in as bad a condition as before.

It is probable that on an old style of pavement, such as cobblestone or granite block with poorly filled joints, these machines will give the best quality of work but it is expensive and not conducive to low cost of pavement repair.

The squeegee system is much like the horse-drawn sweeping system. In place of the rotary broom is substituted a cylindrical scrubber with rubber strips attached in a spiral formation. Its use is preceded by a

sprinkling wagon or flusher, preferably the latter. The squeegee wagon also carries a water tank which supplied water for the actual scrubbing operation. When the refuse finally reaches the gutter it is commonly pushed or floated to a manhole and dumped in a sewer.

The squeegee does its best work on light material and is therefore in this respect more efficient than a broom, but on the other hand the squeegee would be lost in a dirty street covered with every sort of coarse refuse. While scrubbing of the pavement with a rubber squeegee is possibly less harmful to the pavement than the grinding action of a broom working in mud, it necessitates the use of a greater amount of water, which is harmful, particularly when the squeegee is preceded by a tank by which water is placed on the pavement by force. The cost of the great volume of water used is seldom calculated.

Flushing of streets has appealed to the layman, but it has serious defects. The word may be used to mean flushing by hand with a hose attached to a nearby hydrant but more properly it refers to the use of a truck on which is mounted a large tank from which water under pressure is pumped onto the street. Its effectiveness depends on the angle at which the water is thrown from the nozzles. Such a method depends for its efficacy on the force of the water. There is usually enough force in the water to carry the greater portion of the dust and fine refuse to the gutter where a good portion flows to a catch basin or is easily pushed there. When used on heavy refuse the force of the water is sufficient to move the matter only a few inches where it then remains while the water flows on to the gutter.

Motor-driven flusher with sprinkler attachment.

One of the largest flushers in America holds 2,500 gallons of water and seven minutes are required to fill it. Some appreciation of the amount of water used in a day and of the rate at which it is placed on the pavement can be gathered from the fact that it takes only four minutes to empty the tank. Aside from the amount of water used, the value of which is rarely considered, there is the cost of additional cleaning of catch-basins and sewers necessitated by virtue of the fact that disposal of the refuse is accomplished by means of the sewers.

Aside from the expense items of water and cleaning of catch-basins and sewers there is yet another item that should properly be charged against the method. This is the additional cost of pavement repair due to the use of water under pressure. Any exact estimation of this is, of course, impossible, but it should have an effect on the decision of municipalities to use or abandon this method.

A centrifugal pump usually supplies the force for placing the water on the pavement. This may either be driven from the motor of the truck or from an auxiliary motor, the latter being preferable. Now, pavement is made of aggregates bound together in the most thorough fashion. The finer

A vacuum machine used at San Diego, California.

materials are placed on the surface to produce a smooth roadway. Water forced on the surface will eventually wash out some to the binding material. If there is a weak spot in the pavement the water will find this, and under pressure develops this in time into a depression and finally into a pot-hole. This is particularly true where pavements abut on car tracks. It is difficult and almost impossible to secure a tight bond here and the water has a chance to work in and get at the sub-surface.

Hand flushing has the advantage

that the stream of water can be directed at any place long enough to move the refuse and can follow it into the catch basin with whatever amount of water is necessary to place it there.

Sweeping if followed by flushing would give a nearly perfect result as far as the actual cleaning is concerned, and even simple flushing is to be preferred to any of the methods thus far considered.

Motor driven combination machines settle the dust by means of a spray, cleans the street by sweeping, collects the refuse and carries it away. The machines are so constructed that all these operations go on simultaneously in different parts of the machine. Most of these machines now in operation are unable to get within ten inches of the curb, and with these the refuse in the gutters is either hand swept into the path of the combination machine or hand swept or flushed after the street itself has been cleaned.

Combination machines use only a small amount of water, not over three hundred gallons per hour. This is atomized and used only in quantities just sufficient to lay the dust. Five minutes after the machine has passed the street is dry. This minimizes water damage to the pavements and adds to the pleasures of autoists who object to wet and slippery streets.

The combination machine gets all the refuse and most of the dust. The combination machine is not a motor

Combination machine with sand spreading attachment—used in rainy weather to prevent slippery streets.

truck and it is usually poor policy to run it to a dump for the purpose of emptying the collection hopper. It is preferable to go to some quiet side street and transfer the refuse to a motor truck. Cleaning with motor-driven combination machines is no more and probably less costly than flushing, if the collateral cost of water, pavement repair, and sewer cleaning are added to the cost of the latter.

In the dim distant future city streets may be cleaned by vacuum. The machines of this type so far developed either suck the refuse directly from the pavement or by the use of a broom loosen the refuse, agitate it, and permit it to be placed in the col-

lection box by means of suction. Machines of these types will not remove heavy refuse and a man must be employed to pick up stones and other heavy materials and place them in a collection box provided for the purpose. Vacuum machines work at their best under absolutely dry conditions. Machines without a broom have no effect on refuse that is stuck to the pavement.

As far as ability to handle various types of refuse on different kinds of pavement is concerned, the vacuum is nearly a one-class machine. It is admittedly in its developmental stages at present. The problems involved are engrossing ones.

For the present and for the next

few years the motor-driven combination machine represents great progress toward a standard method. Casting aside its present defects it must also be admitted that a perfect vacuum system would come nearer meeting the requirement of an ideal street cleaning system than any other.

Street cleaning is not a simple problem. The variety of street surfaces and the many kinds of material that accumulate on them make it necessary that the ideal system shall handle both large objects and fine dust on rough as well as smooth pavements. This is a hard contract to fill. For economical, aesthetic, and sanitary reasons the attempt should be made.

Resolutions of the Oriental Red Cross Conference

THE following resolutions were adopted by the Oriental Red Cross Conference held at Bangkok, Siam, November 29-December 8, 1922. The delegates in attendance represent the Red Cross societies of Australia, China, Great Britain, India, Indo-China, Japan, Java, the Philippines and Siam. It is most important to note how well the general Red Cross program as it is visualized in Europe and America fits in with oriental conditions.

The Oriental Red Cross Conference in accordance with the request of the League of Nations, has considered what assistance Red Cross Societies can give in the matter of combating the abuse of opium and other noxious, habit forming drugs and urges that simple instruction regarding the dangers attendant upon such abuse be given a prominent place particularly in work among children, in any program of popular health instruction undertaken by national Red Cross Societies in countries where the abuse is prevalent.

The Conference considers that this work, if success is to attend it, must have the full support, material and moral, of the governmental authorities in the countries in which it is undertaken and recommends to the Secretariat of the League of Red Cross Societies that it requests the League of Nations to aid in securing such support from its state members.

The Oriental Conference desires to record its approval of the program of action adopted by the members of the League of Red Cross Societies at the General Council Meeting of March, 1922, namely, to create an intelligent demand for better health conditions and an increasing knowledge of the means of securing them, chiefly through the development, with the cooperation of the League Secretariat, of Popular Health Instruction, Public Health Nursing and Junior Red Cross.

The Oriental Conference recognizes

that the program in its entirety is not capable of being applied in all countries at the present moment, but it is convinced that an adaptation of one or more of the activities indicated is not only possible but very greatly to be desired. The Conference, therefore, recommends that each national society here represented take into consideration at once the question of which method should be adopted, having regard to the conditions of its country.

The Oriental Conference desires to record its conviction that the demonstrations and the reports which have been made before it and which have been carefully studied by the delegates have shown that popular health instruction is practicable within the present scope of every society here represented and that a successful method can be found to meet any conditions now existing in the Orient.

The Oriental Conference recommends that each national society here represented promote the formation in this country of a Nations Health Council for the co-ordination of all health educational work by governmental agencies and non-governmental agencies of national scope.

The Conference considers that such a national health council should be an organ for the purpose of mutual consultation among the agencies represented and should not undertake any program of health work as an operating organization.

The Conference requests the Secretariat of the League, in consultation with such governmental and other agencies as it may find useful, to make a study of the experience and possibilities of such health councils.

The Oriental Conference considers that the creation of an intelligent demand for better health conditions and an increasing knowledge of the means of securing them should eventually become a function of government, but it desires strongly to affirm its conviction that Red Cross societies should undertake to arouse public interest in this direction and to demonstrate

practical methods of meeting the need with the intention of withdrawing from any specific activity whenever governmental agencies undertake it as a permanent responsibility.

The Oriental Conference recommends that national societies here represented shall, in undertaking Junior Red Cross activities, keep clearly in mind the cardinal principles of organization enunciated by the Secretariat of the League.

The Oriental Conference, having taken into account the special educational conditions existing in some oriental countries, considers that the organization regulations of junior membership should provide that children who are unable regularly to attend school may be given an opportunity to participate in junior membership activities by associating themselves, as circumstances may permit, with children of the same age who are enrolled in the school units. It requests the Secretariat of the League of Red Cross Societies to make a special study of methods, by which problem of children so situated may be solved.

The Oriental Conference recommends that each Society represented, form, as soon as possible a committee of educational and health authorities to advise the direction of the National Society as to when and how Junior Red Cross work may be begun.

The Oriental Conference urges every society represented to undertake at once the formation of a committee on public health nursing in order that the special conditions of the country may be studied and a program of educating the public in regard to its health by the method of Public Health Nurses may be begun if it is deemed desirable.

The Conference urges National Societies in the Orient to avail themselves, not only of the technical studies made upon this subject by the Secretariat of the League, but also of the facilities for training representatives of their countries in this work, which are offered by the International Course of Training in London.

Energy Expenditure in the "Daily Dozen"

BY MARGARET M. JUSTIN, LABORATORY OF APPLIED PHYSIOLOGY, YALE UNIVERSITY, NEW HAVEN, CONN.

VARIOUS setting up exercises have long been practised rather generally in military and athletic organizations. Many individuals also use such exercises more or less spasmodically. Recently, owing to the prestige of Mr. Walter Camp in athletic matters, a series of exercises, devised by him and known as the "Daily Dozen," has been very widely introduced. Phonographic records which include vocal directions and musical accompaniment are also extensively utilized.

The exercises are described as designed, not to take the place of daily outdoor exercise, but rather to exercise the little used parts of the system, and in particular to improve the tonus and efficiency of the thoracic and abdominal viscera. Many persons of sedentary habits, or of impaired physique and even with weakened hearts, are trying the "Daily Dozen," and in some cases are practising it regularly. It is, therefore, important to know the amount of energy expenditure involved in the performance of these exercises.

The chief subject of the observations reported below was the writer, a woman of sound physique, age thirty years, height 167 cms. (5 ft. 6 in.), weight 67.3 kilos (148 pounds), accustomed to the active life of a graduate student in experimental science, but not in strict physical training.

As a control and background for the observations, the energy expenditure was first determined while the subject was sitting at rest and again while walking at what was as nearly as possible the maximal speed that could be maintained. From the respiratory volume during walking it is clear that any greater exertion would have involved distinctly labored breathing. The method of observation consisted in the use of the Douglas bag with mouth piece, and inspiratory and expiratory valves. The time of beginning and end of each observation was taken by means of a stop watch, and the volume of air in the bag was measured by means of a Danish wet meter. A sample of the air was analyzed in duplicate for oxygen and carbon dioxide. The figures from these analyses and from the gasometric measurements were then reduced to the per minute consumption of oxygen and expiration of carbon dioxide at 0° C, and 760 mm. The

respiratory quotient was calculated and the expenditure of energy in calories per minute.

The different exercises of the "Daily Dozen" were performed on other days and similar records taken of them. The data obtained are shown in Table I.

A glance at the right hand column of this table shows that, while some of the exercises are quite moderate in character, others involve a very considerable energy expenditure or, in everyday language, a very considerable muscular exertion. This is particularly true of the "crouch,"

TABLE I.—ENERGY EXPENDITURE AT REST, WALKING, AND WHILE PERFORMING THE VARIOUS EXERCISES OF THE "DAILY DOZEN."

Type of Exercise and Remarks	Respiration Vol. Liters per min.	O ₂ cc. per min.	CO ₂ cc. per min.	R. Q.	Cal. per min.
Subject sitting at rest for 20 min., at the end of this time determinations made	9.7	363	329	0.93	1.8
Sample taken under same circumstances 10 min. later	10.2	351	286	0.81	1.69
Subject walking 3.26 miles per hour on cement floor. Sample taken from moment of start to end of 2nd minute, a rapid walk, much more than the ordinary pace for this subject.	29.2	1285	934	0.73	6.06
Same as previous but sample taken from 3rd to 5th min.	29.1	1339	931	0.70	6.28
Continued the walk for total of 10 min. and then sat down. Sample taken immediately while sitting for two min.	14.8	548	385	0.70	2.56
The wave, 2 min. and 56 sec. Air sample taken throughout the period. Subject was more fatigued after the 2 nd min. than after walking 10 min. as in previous test.	22.3	981	669	0.70	4.6
After a rest of 20 min. the subject repeated the exercise for 4 min. with sample throughout.	20.5	882	615	0.70	3.9
The Grind for 5 min. Sample taken during first 2 and last 2 min.	20.4	678	530	0.79	3.2
Sample of first 2 min.	22.8	843	684	0.80	4.1
Sample of last two min.	16.0	592	480	0.81	2.84
The Grasp for 5 min. Sample taken during first 2 min.	16.6	634	551	0.85	3.08
Sample taken during last 2 min.	16.7	584	434	0.81	2.56
The Grate for 5 min. Sample taken during first 2 min.	18.9	605	491	0.81	2.90
Sample taken during last 2 min.	16.7	616	468	0.76	2.90
The Crawl for 3 min. Sample taken during first 2 min.	17.0	699	514	0.78	3.32

Total energy expenditure in doing the whole series in 13 min.					41.9
Energy expenditure for 13 min. during sitting rest					22.7
Cost of "Daily Dozen"					19.2

which consists of deep knee bending. It is true also to a slightly less extent of the "weave" and the "wing," in which the trunk is quite vigorously turned and flexed. In the "crouch" the energy expenditure considerably exceeds, and in the other two mentioned, it approaches that of rapid walking. For the whole series the energy expended would exceed that during sitting rest by 22.7 calories, the equivalent of a lump of sugar.

The comparison of these exercises with the exertion of rapid walking given, however, a decided under-estimate of their vigor. Walking is the most efficient exercise of which the body is capable. Very large muscle masses—those of the legs and to a considerable extent also those of the trunk, arms, and neck—are utilized. The distribution of the work over such an extent of the motor mechanism is sufficient to indicate that only a small part of the total energy expended is contributed by any one muscle. On the other hand, the smaller number of muscles taking part in an artificial exercise requires that, if the total energy expenditure is approximately the same as that in walking, the particular muscles involved must make a very much greater exertion than do any of the muscles in walking.

From this point of view some of the exercises, particularly those above mentioned, and to a considerable extent others also, are seen to involve a decidedly strenuous exertion. It is an exertion also which for the beginner is of a sort quite different from those which the muscles habitually perform. It is therefore correspondingly more severe. The case may be here mentioned of a man of fifty or rather better than average strength and health who was made too lame to walk for several weeks after doing the "crouch."

A few observations were also made upon two men and two women in order to determine the relative vigor with which the entire series of exercises was performed when the phonograph records were used simultaneously in comparison with their performance in silence without the music and vocal directions. In these observations, (Table II) the energy expenditure was not determined during the exertion, but during the five minutes immediately following. This method offers of course no exact information regarding the amount of energy expended during the exercise. But as it is now known¹ that the recuperative processes in muscle proceed for a period after external work is termi-

nated, such observations may be utilized for the comparative purpose to which they are here put.

As a glance at the last three lines of Table II shows, the average pulse rate was increased to 150 per cent of the resting value by the exercises with music and only to 125 without music. The volume of air breathed and the energy expenditure in calories varied, as is usually the case, in closely proportional amounts, namely 269 and 262 per cent of the resting value after exercise with music and 165 and 164 without music. The figures for ten minutes after the exercise show similar relations, but are not quite so closely parallel.

As Professor Henderson and his collaborators have emphasized in previous papers² from this laboratory, the only index of respiration that has any considerable value is the measurement of the volume of air breathed per minute. The rate of breathing by itself is not worth counting, but as the data here reported demonstrate, there is the most direct and general value to be derived from measurement of the volume of air breathed.

The amount of energy expended

siderably. In some of them it is scarcely greater than that of slow walking; in others it exceeds the energy expended in very rapid walking.

The energy in these more strenuous exercises is expended by rather small groups of muscles unaccustomed to such strain, and involves for them therefore an excessive exertion.

While some of the exercises are mild, the use of the more strenuous parts of the series by the aged or by those in poor condition, should be begun with caution, and should be increased from day to day very gradually. Indeed for such persons, certain of the exercises, particularly the "crouch," was better omitted.

The phonographic musical accompaniment and directions increase the pleasure and vigor of the performance of these exercises, and are to be commended for all except the more strenuous numbers in the series.

Finally, the writer desires to express her thanks to Professor Yandell Henderson at whose suggestion this investigation was undertaken, to Dr. Howard W. Haggard for instruction in methods and assistance in the performance of the work, and to Mr.

TABLE II.—AFTER-EFFECTS ON PULSE, RESPIRATION, AND ENERGY EXPENDITURE, BY PERFORMING "DAILY DOZEN" WITH AND WITHOUT PHONOGRAPHIC DIRECTIONS AND MUSIC.

Subject	Symptoms Measured	With music			Without music		
		At rest sitting	After Daily Dozen	10 min. later	At rest sitting	After Daily Dozen	10 min. later

Averages in per cent of resting values.		100	151	117	100	125	112
		100	269	143	100	165	121
		100	262	149	100	164	104

while doing the various exercises of the so-called "Daily Dozen" has been determined. It may be estimated at about twenty-three calories over the expenditure during sitting rest, or, in terms of diet, as equivalent to about six grams, or one small lump of sugar.

The energy expended in the different exercises of the series varies con-

Walter Camp for a fund sufficient to cover the rental of the phonograph records.

The New York State Industrial Commission estimates on the basis of records for the year 1922 that one-half of the accidents in our factories, with the resultant loss of \$50,000 a day to industries, is due to ignorance of the English language.

Public Health in England

THE annual report of Sir George Newman, chief medical officer of the Ministry of Health, for 1921, gives an interesting picture of the encouraging progress of public health science across the water. The leading causes of death in England during 1921 were as follows: Diseases of the heart, 12%, diseases of the nervous system and sense organs, 11%, cancer, 10%, pneumonia, 8%, tuberculosis of the lungs and bronchitis, each 7%, premature birth and diseases of early infancy, and of old age, each 6%. It is interesting to notice the relatively low place occupied by bronchitis and pneumonia as compared with our American experience. Infant mortality is nearly as low as last year (83 per 1,000 births), but the mortality among women in childbirth still remains high, showing little or no improvement in the last thirty years. An age analysis indicates very encouraging results in the lower age periods, but in comparison with Sweden the death rate in adult life is not satisfactory. Seventy years ago the expectation of life at forty-five was less in Sweden than in England but today the expectation of life at forty-five in Sweden is three years higher than that in England.

Very interesting data are presented as to the result of medical examinations of school children and of the workings of the National Insurance Act. In the schools about 40% of the children are found to be defective, distributed about as follows: malnutrition, 3%, defective vision, 10%, diseases of the nose and throat, 15%, enlarged glands, 6%, serious dental disease, 20%, anemia, 3%, deformities, defective hearing and skin disease, 2% each. It is obvious that the standard of malnutrition is much less severe than that commonly used in this country. Under the Insurance Act it appears that the working population of England and Wales loses through sickness upwards of 278,000 years of working time or about 2% of the total working time of the group involved, a result checking almost exactly with the observations made by the Metropolitan Life Insurance Company in this country. The average number of insured persons for each physician on the insurance panel was approximately one thousand and never exceeds three thousand.

It is encouraging to notice that there are now 1,869 infant welfare centers in England, 3,378 health visi-

tors, 421 tuberculosis dispensaries, 339 tuberculosis officers, 18,943 beds for tuberculosis, and 194 venereal disease treatment centers. In regard to the latter it is of much interest to note that the number of new cases which rose steadily to 105,185 in 1920, fell to 84,715 in 1921 although the total number of clinic attendances rose from 1,488,514 to 1,653,692.

Sir George makes a strong plea for the control of public health work so that we may be certain that full value is realized for every dollar that is expended. He points out, however, that of the total taxes for England and Wales, 20% is spent for education, 17% for highways, 14% for poor relief, 17% for sewers, removal of house refuse, water supply, parks, baths, cemeteries, isolation hospitals and vaccination, and only 1% for the campaigns against maternity and child welfare, tuberculosis and venereal diseases. He cautions us that we must be patient in waiting for the fruits of preventive medicine. "In a true sense

the nation can buy health, but the 'goods' are not delivered on the date of payment. Public expenditure on national health is like expenditure on a life-boat or a fire engine; even more, it is like a long-term investment. It yields its interest with absolute certainty, a thousand fold, but only in the course of years and sometimes only in the course of generations. It is money hidden in maternity, in good schools, in pure food, in clean streets, in sanitary houses, in an abundant water supply, in dispensaries, hospitals, and sanatoriums, and in the vast network of a sanitary and protective cordon in every village and city in the land. Its efforts are unappreciated until they are withdrawn. Yet without this investment the nation is bankrupt."

That naturopaths are physicians has been upheld in the appellate court of California. In view of this decision the state prohibition director has requested National Prohibition Commissioner Haynes that naturopaths be accorded the privilege of obtaining whisky prescription books.

Buying Vitamins of the Grocer

The mother and children who go to the market with a basket, and who do not pour the vegetable juices down the sink drain pipe, will not suffer from vitamin deficiency in the summer time.

Health center activities at the Massachusetts-Halifax Health Commission continue to interest the people of Halifax and Dartmouth. In February 3,374 instructional home visits were made by public health nurses and visiting housekeepers to a total of more than 2,100 individual homes. In the same month 1,047 babies under two years of age were being supervised by the health staff in their homes. The medical service shows

929 medical, dental, and nursing consultations, more than half of these being in the nutritional classes. The above picture is reproduced from a highly interesting booklet on "Vitamins," distributed by the Commission for the instruction of the mothers in the selection and preparation of foods. "Use more natural foods," states the booklet; "cook for as short a time as possible; and don't let the drain pipe be better nourished than your family."

Digest of Sanitary and Hygienic Advance

Bacillus Welchii in Bread

A commercial bread starter recommended for the purpose of securing a constant inoculum of a gas forming bacterium in the preparation of salt-rising bread, has been found to contain organisms of the *B. welchii* type in numbers of about one thousand per gram. The addition of this starter to boiling hot milk and an over night incubation result in a light frothy mass in which the prevailing organism was the Welch bacillus and having from one to one hundred million bacteria per gram of material. Small quantities of bread from the interior of the loaves prepared in this way by several bakeries yielded the gas bacillus in almost every instance.

Cultures from the bread possessed only a low grade of virulence for guinea-pigs, while a type of *B. welchii* originally obtained from a wound was highly pathogenic. Loaves of bread made with the pathogenic strain were comparable to those made with the commercial starter.

Though commonly found in the intestinal tract of man and widely distributed in nature, this organism is known to be a dangerous pathogen associated with war wounds and claimed by some to be the cause of many cases of diarrhea. Koshier (*J. Infect. Dis.*, March, 1922, 32, 3, p. 208) thinks that in view of the many disputed points regarding *B. welchii* that such uses may be considered by some a public health problem and that the choice of such organisms whose use is beyond question, would be the safest course.

Creosote Oil a Mosquito Repellent

Observation that bridges in Yazoo County, Miss., constructed of timbers treated with creosote oil, were free from *Anopheles* mosquitoes while other bridges nearby made of untreated timbers were resting places for many, lead Coogle to test the effect of this oil as a repellent in the poorly constructed tenant houses which cannot be properly screened. The oil was applied in the quantity of one gallon to 420 square feet. Observations made ten weeks after application seemed to indicate that the creosote was still active.

The colored people who live in this type of house do not object to the application, no ill effects were noted, and it is certainly preferable to the

smudges of rags, leather, and feathers so universally used by these people to keep the mosquitoes away while they get a few hours sleep. (*Pub. Health Rep.*, March 9, 1923, 38, 10, p. 437.)

Phagocytosis of Carbon and Quartz

The findings of Fenn (*J. Gen. Physiol.*, Jan. 20, 1923, v, 3, p. 311) in regard to the phagocytosis of quartz and carbon particles are of interest in relation to the industrial dust hazard. The results show that leukocytes ingest quartz particles more readily than carbon in acid solutions, and carbon more readily than quartz in alkaline solutions. In the presence of acacia carbon is always preferred to quartz even in acid solutions. Manganese dioxide particles are ingested with extraordinary rapidity as compared with manganese silicate or quartz. The leukocytes are not attracted toward carbon or quartz particles but manganese dioxide exerts a distinct attraction for them. Spores of *Penicillium* are ingested more readily than quartz. Particles of quartz under one micron in diameter are not ingested as readily as larger particles of the same material.

The technic of the experiment consists of mixing the various particles with the peritoneal exudate from the rat and making counts on a warm stage.

Codliver Oil Inhibits Tubercle Bacillus

An attempt to discover whether the action of codliver oil, which has long been associated with the treatment of tuberculosis, has in relation to this disease other than a nutritive value, is reported by Campbell and Keiffer (*Am. Rev. Tuberc.*, Dec. 1922, ix, 10, p. 938).

These investigators found that codliver oils have a "definite inhibitory and bactericidal action on virulent tubercle bacilli; cottonseed oil, used for control, has not inhibited the growth of the bacilli to the same marked degree, and has shown no bactericidal action; tubercle bacilli cultivated on cottonseed oil media for six weeks were able to grow and produce tuberculosis (in guinea pigs), whereas tubercle bacilli cultivated on codliver oil media for the same length of time were not able to grow when transplanted or to produce tuberculosis."

Codliver oil also inhibited the

growth of a *lepra* bacillus, an avirulent tubercle bacillus, and *B. typhosus*. Aqueous extracts of codlivers showed neither inhibitory nor bactericidal action. After contact with codliver oil "the granulation and granular appearance of tubercle bacilli and allied bacteria" was increased. Similar changes have before been noted in the bacilli from sputum of patients treated with sodium morrhuate.

The oil extracted with as little heat as possible and not refined in any way, seemed to have a more potent action than commercially refined oil or oil extracted by heat.

Recording Kata-thermometer

A recording Kata-thermometer which produces continuous records has been devised by Dr. Schuster of the British National Institute for Medical Research. If sufficient orders are obtained, the Oxford Scientific Instrument Company will undertake its manufacture. The accompanying illustration shows the nature of a record made on an outside window ledge.

The Kata-thermometer recently devised makes a continuous and easily observed graphic record. Part of record made on an outside window ledge.

The rapid fluctuations in the cooling power of outdoor air are highly significant. According to the New York State Commission on Ventilation such small fluctuations, from minute to minute, are an important factor in making window ventilation more pleasing than the uniform conditions prevailing under the use of mechanical ventilation.

This new conception of ventilating that requires new instruments for continuous observation and permanent record of fluctuating conditions is met by the apparatus described.

Influence of Alcohol on Progress of Pneumonia

To determine what influence the use of alcohol might have on the death rate, 3,422 cases of lobar pneumonia occurring during eight years at the Cook County (Illinois) Hospital were studied by Capps and Coleman, (*Journal A. M. A.*, March 17, 1923, 80, 11). It was found that the mortality was considerably higher in moderate users than in light users or abstainers, and that the mortality in excessive users was much higher than in moderate users. The average age of the moderate group was about five years greater than that of the abstainers or light users, and the average age of the excessive group was three years more than the moderate. The maximum range between the first and third group was eight years. This would, therefore, explain a certain increase of mortality in the second and third groups over that in the first group. To eliminate the age factor entirely from the problem, the mortality rate was reckoned separately in each group by decades. A comparison of the death rate in the same decades of the three groups shows a remarkable increase of the moderate users over the light users or abstainers, and a still greater increase of the excessive users over the moderate. It is impossible to calculate the effect of legislative prohibition, but in recent years there has been an increase in the proportion of abstainers or light users, and a corresponding decrease in the number of excessive drinkers. The practical disappearance of delirium tremens in recent years, as compared with its frequency before prohibition, also bears testimony to a lowered rate of alcohol consumption. It is the authors' belief that it may be properly concluded that if all these patients had been restricted to abstinence or to the light use of alcohol, 439 patients who died would have been saved.

Schaefer Prone Pressure for Resuscitation

Report II of the Commission on Resuscitation from Carbon Monoxid Asphyxia (*J. Indust. Hyg.*, March, 1923, *iv*, 11, p. 463) shows that no evidence has been obtained from representative gas companies that either the lung-motor or the pulmotor is superior to the manual prone pressure method of artificial respiration, while the evidence from hospitals indicate that any method that drives air by positive pressure into the lungs may be a source of danger. Further investiga-

tions are under way. At present the best procedure consists of immediate use of prone pressure in non-breathing cases, supplemented as soon as possible by oxygen carbon-dioxid inhalations given through a suitable inhaling device.

Diphtheria Prevention in Boston

Progress on the Schick testing and toxin-antitoxin activities of the Boston Health Department reported by Ceconi (*Boston M. & S. J.*, Jan. 25, 1923, 188, 4) show 24,458 individuals tested. Fifty-two and seven-tenths of the Schick tests indicated susceptibility; 47.2 per cent revealed immunity; and 19.7 gave the pseudo-reaction showing protein sensitiveness.

Re-Schicking a group of 261 positive reactors gave fourteen positives showing an immunity of 96.9 per cent six months after the administration of toxin-antitoxin.

Out of 1,663 cultures from the noses and throats of positive reactors, 103 or 6.2 per cent were positive and all non-virulent. A thousand cultures from negative reactors gave fifty-seven or 5.7 per cent positive and all likewise non-virulent.

Eaton (*loc.cit.*) states that in the North End, where living conditions are crowded, only 15.2 per cent out of 591 children tested were susceptible, whereas in Jamaica Plain, Allston, Brighton, and Roslindale 72 per cent of the 1,957 tested were susceptible to diphtheria. There is a high percentage of immunity among Italian children no matter where they live. Another observation of interest is that familial tendencies are not uncommon.

Botulism in Scotland

An outbreak of botulism occurred at the Loch Maree Hotel in August, 1922. Though the details were widely reported in the newspapers at that time, Monro and Knox have thought it well to have an exact account in the medical literature of this outbreak, the first of its kind known to have occurred in Britain.

Eight individuals, six guests and two gillies, were taken ill and all died. The shortest incubation period was fourteen hours and the longest was forty-three, but may have been less as the gillies probably ate the infected food some hours later than the guests. The longest period of survival was six and a quarter days and the shortest fifteen to seventeen hours. Sandwiches made of potted wild duck

were apparently responsible. Some individuals ate the sandwiches and were not ill. This was probably due to the fact that two pots of the duck were used. The histological findings from the examination of a part of the brain of one of the victims were in accord with the diagnosis of botulism, and *B. botulinus* and its toxin were found in the remains of one of the pots of wild duck paste. (*Brit. M. J.*, Feb. 17, 1923, 3242, p. 279.)

Relation of Acidity to Intestinal Bacteria

Two explanations have been proposed in accounting for the facts that animal protein diet encourages the growth of proteolytic types of organisms in the intestine while the addition of lactose or dextrin stimulates the development of the aciduric forms. One of these explanations assumes that the carbohydrate offers a readily available source of energy for both types and as a result fermentation instead of proteolysis occurs. At the same time acid is produced which tends to make the environment unfavorable for the proteolytic types. The other view assumes that acidity plays no part in the elimination of the proteolytic types.

Cannon and McNease (*J. Infect. Dis.*, March, 1923, *xxvii*, 3, p. 175) have conducted feeding experiments with rats, killing them after some days, determining the hydrogen-ion concentration of the caecum and lower colon, and making microscopic and cultural examinations of the contents of the intestine. With high animal protein diet the acidity of both caecum and colon is pH 7.0 to 7.1, whereas the addition of lactose to the diet may produce a pH of 4.6 in the caecum and 6.2 in the lower colon. The conversion of the intestinal flora varied with the acidity. With an increase of acidity the gas producing proteolytic types are replaced by the aciduric. Determination of the acidity of the feces is of slight value in interpreting the acidity of the intestinal contents higher up.

Blood Destruction in Exercise

Broun has demonstrated (*J. Exper. M.*, Jan. 1, 1923, *xxvii*, 1, p. 113) "a great decrease in total circulating hemoglobin and red cell volume in dogs, long maintained under sedentary conditions, when they are exercised vigorously during several consecutive days. This seems to be consequent on increased blood destruction, unrepaired for the time being."

Infant mortality in Bombay during the year 1921 was 666 per 1,000 births. (*Lancet*, March 10, 1923, 1, 5193, p. 505.)

Sterile Underground Water Samples

The problem of obtaining samples of underground water by a technic that is surgically aseptic has been simplified by H. R. Crohurst. (*Trans. 20th Annual Conf. State and Territorial Health Officers with the U. S. P. H. S.*, P. H. Bull. No. 128, Dec. 1922.)

As shown in the accompanying diagram the sampling well consists of a one-eighth inch pipe of the desired length with a copper screen at the lower end and an elbow with a screw plug at the upper end. A hole is sunk in the ground by means of a one-eighth inch pipe having a point screwed on the lower end, or if the resistance is great a solid iron bar may be used. This plunger is then cautiously withdrawn and the well pipe inserted. The inside of this pipe can be chemically sterilized in the laboratory and the outside can be flame-sterilized in the field with a plumber's torch. If the screen becomes plugged an automobile tire pump attached to the upper end of the pipe will free the screen.

A device which simplifies the task of obtaining samples of underground water under surgically aseptic conditions.

A pitcher pump is used to draw the samples. On the bottom of this is a short blind pipe to hold the priming water. This pipe is tapped laterally by a line which exhausts a suction flask which in turn exhausts the sample bottle connected to the top of the well pipe.

Under favorable circumstances two men have demonstrated that it is possible to install twenty-one of these wells in about an hour.

A larger type consists of a one and one-quarter inch pipe having a check valve at the top and a reservoir above the valve. The pump exhaust directly from the reservoir from which samples are then removed through a one-eighth inch stop-cock.

Value of Existing Cancer Statistics

Among 3,712 necropsies reviewed by Wells, (*Journal A. M. A.*, March 17, 1923, 80, 11) there were 545 cases of malignant disease, or 14.7 per cent. These figures cover all forms of malignant tumor, including cerebral gliomas and endotheliomas. The summary of these records in respect to the question, How many cancers are recorded in the vital statistics that would have been omitted but for necropsy? shows that 367 cases were correctly diagnosed as malignant tumors and 178 cases were not recognized as malignant tumors. In thirty-three cases cancer was diagnosed as present when no malignancy was found at necropsy. In 578 cases (367, correct; 178, omissions, and thirty-three, erroneously called cancer), there were 211 incorrect diagnoses, or a diagnostic error of 36.5 per cent. Eighty-two external tumors were correctly diagnosed and ten external tumors were not recognized. Two hundred and eighty-five internal tumors were correctly diagnosed, and 168 internal tumors were not recognized. These figures indicate that, as is to be expected, few of the errors are made with external tumors. The error in diagnosis of internal tumors, 37.1 per cent, was almost exactly the same as that reported for inaccessible tumors in the London hospitals, 37.3 per cent. Primary carcinoma of the liver and lung most often escaped recognition. The sort of errors in diagnosis varied with the site of each tumor. The commonest erroneous diagnoses were: cirrhosis, twenty-one; pulmonary tuberculosis, eighteen; heart disease, usually myocarditis, eleven; pneumonia, seven; nephritis, six; jaundice, six; paresis, six; generalized tuberculosis, five. A study of the distribution of all the tumors reveals, first, the great predominance of tumors of the alimentary system, which constitute more than half of all the cases. Wells states that this study shows emphatically the lack of value of all recorded vital statistics on cancer; that at the present time there are no reliable statistics relative to the frequency of cancer as a cause of death. The futility of attempting to learn anything concerning heredity from such statistics is even more glaringly apparent. A single error in diagnosis may lead to entirely erroneous conclusions in the study of the influence of heredity on cancer in a given family. Such accuracy is obviously not present in any existing study of human heredity in respect to cancer.

Sewage Disposal at Trenton

A recent report on sewage disposal of the city of Trenton, N. J. by George A. Johnson, strongly recommends the so-called direct oxidation process for the treatment of the sewage of Trenton. According to Mr. Johnson's estimates the process would cost about the same as an Imhoff tank sprinkling filter plant and would be slightly cheaper than an activated sludge plant and is preferred to the sprinkling filter installation on the ground of nuisance. The direct oxidation process has been editorially discussed in THE NATION'S HEALTH (November, 1922).

Stability of Vitamin Content of Cod Liver Oil

An abstract of an article by Poulsen in *Norcks. Mag. for Laegevidenskaben*, January, 1923, p. 35, (*Brit. M. J.*, March 3, 1923, 3244) states that heating cod liver oil for sixteen hours at 98 degrees centigrade leaves the vitamin content of the oil practically unchanged. Bubbling air through the oil destroys the vitamins in a few hours. Exposure to air at ordinary temperatures is also injurious; a thin layer of oil poured on a glass plate was inert after fourteen days. Time alone has little effect as is shown by the fact that one of the most potent samples examined had been bottled for three years. Emulsified forms of the oil expose more surface to possible air contamination and for the chance for vitamin loss is increased. The liver of the male cod is found to contain more oil than that of the female. The liver oil of certain other fishes was also found to be as rich in vitamin A as is cod liver oil.

The author cited a case showing the benefit to be derived from giving cod liver oil to a nursing mother.

Syphilis in Industrial Disablement

The cost of syphilis to industry and the attendant danger to the travelling public are shown in an analysis of 291 physical surveys of railroad employees made by Edmunds (*J. Indust. Hyg.*, Jan. 1923, IV, 9, p. 380.) The diagnosis of syphilis was based on the physical findings, blood and spinal fluid, Wassermann test. There were 291 surveys made and the blood was examined in 223 cases, of which 187 gave a negative reaction and 35 a positive. Of the total number of patients, 291, 12 per cent had syphilis.

Of the 222 cases in which Wassermann test was made, 15 per cent gave positive results. In the 35 cases of these were 32 positive blood Wassermann's and 3 negative with positive spinal fluid. There were 14 positive spinal fluids and 2 negative; in 19 cases the spinal fluid was not obtained. In 11 cases both blood and spinal fluid were positive. Twelve patients gave a definite history of syphilis. Nineteen had definite cerebrospinal syphilis; of this number, 14 were trainmen and had to do with the operation of trains. Of the 35 patients with syphilis, 15 are now permanently disabled; and 4 are dead. The total amount of time lost by these 35 employees up to May 1, 1921 was 13,946 days. The largest number of days lost by one person was 2,003, the smallest 30, the average being 410. The cost to the relief department for the same period was \$25,296, the cost to the company as compensation, \$25,415.00, a total of \$50,711.00.

Syphilitic trainmen with an invasion of the central nervous system are inclined to take chances with the public placed in their care. They are liable to attacks of unconsciousness, of uncertain memory, of defective judgment, and to ideas of grandeur. The cases cited are convincing, for example, a telegraph operator who could not copy a message correctly and an engineer who ran by a signal and caused a collision.

Ascertaining Splenic Index from School Children

Darling, (*Journal A. M. A., March 17, 1923, 80, 11*) emphasizes that schoolchildren can be utilized by the epidemiologist and the health officer not only in estimating the amount of malaria in a community, but also, at times, in revealing the source of the anophelines responsible for their infection. He reports the result of a survey of a Brazilian village. Sixty-six of 150 children had an enlarged spleen. In most instances the spleen was not greatly enlarged, being "palpable" or "one finger's breadth" in size. Blood specimens were not taken from every child, but only from representative age and sex groups. Half the children from whom blood specimens were taken had positive spleens. The plasmodium was nearly always that of tertian malaria. Of the fifty-seven children who lived in the lower half of the town toward the river, forty-two, or 73.7 per cent had palpable spleens, while of the ninety-three children who lived in the upper part of the town and beyond, only

twenty-four, or 25.8 per cent had palpable spleens. This pointed unmistakably to the river margin, as the principal if not the sole focus of the malaria in the locality, and it appeared to eliminate the stream which ran through the village, as well as any possible place farther away from the river, as being of any real importance in contributing to the malaria of the community. Many propagation areas were found in the low places between the river and the town, along the flood plain and in the borrow-pits and ditches near the tile works. Here larvae of *Anopheles argyritarsis*, *A. tarsimaculata* and *A. albinus*, well known carriers of malaria, were found in great abundance. Fewer were found across the river. The larval survey confirmed the indications obtained from spleen examinations, since the propagation areas were found to coincide with the areas near the homes of the malaria-infected children.

The Treatment of Pertussis With X-Rays

Realizing that x-rays were often used empirically Bowditch and Leonard were prompted to try them in the treatment of twenty-six cases of active pertussis (*Boston M. & S. J., March 8, 1923, 188, 16, p. 317*). They have felt warranted in classifying a small percentage as prompt cures, the bulk as relieved, and 10-15 per cent as not relieved. They think it unlikely that there is any bactericidal action but believe that their brief test warrants a more exhaustive study and bacteriological investigation to be carried on in some institution.

Intracutaneous Test for Immunity to Diphtheria

The Kellogg test consists in the injection into the skin of a white guinea-pig of a mixture of equal parts of blood serum from the person tested and a toxin dilution containing one-thirtieth of the L + dose per cubic centimeter. If the patient's serum contains exactly 1/300 unit of antitoxin for each cubic centimeter (the amount stated by Schick as being protective), 0.1 c.c. will contain 1/300 unit of antitoxin. Two-tenths cubic centimeter of the mixture of serum and toxin will, therefore, contain 1/300 unit of antitoxin and 1/300 L + dose of toxin. The combining ratio of these substances is such that there will be free in the mixture 1/300 minimal lethal dose of toxin, which is just sufficient to produce redness without necrosis in

the skin of the guinea-pig. This degree of reaction, as also anything less, constitutes a negative result and indicates immunity. Tests were applied by Kellogg, (*Journal A. M. A., March 17, 1923, 80, 11*), in combination with the Schick test, on 160 persons, in four different groups, each group being tested at one time by the two methods. With two exceptions, the Schick test and the Kellogg test in this entire series of 160 persons tested have agreed so far as uncomplicated Schick tests were concerned. Kellogg is convinced that the Kellogg test is conclusive as showing either the presence or the absence of immunity to diphtheria. Controls are possible which guard against deteriorated toxin and false negative reactions. False negative reactions with the technic described are believed to be an impossibility. Protein reactions do not occur. The test is a central laboratory one, relieving the physician of the responsibility for the interpretation of the doubtful reactions so frequently observed in the Schick test. The test is the one of choice for practitioners having occasion to test a few persons at a time. The disadvantage of the Schick test, under such circumstances, is that no control against false negatives from deteriorated toxin exists. The test is not recommended as a substitute for the Schick test, when large groups are being examined, for the reason that the collection of a large number of blood specimens would be too time consuming, excepting with adults and older children with whom venipuncture can be used.

Neonatal Mortality

According to Levy, a consideration of the statistics of New Jersey by counties shows that those with less than 6 per cent of their births attended by midwives have a neonatal mortality rate ranging from 32 to 54 per 1,000 live births while those with 23 to 43 per cent of their births attended by midwives have a neonatal mortality rate from 29 to 42.

Among primipara the puerperal death rate is lower among women attended by midwives. (*Am. J. Pub. Health, xiii, 2, February, 1923.*)

As a result of the free scheme of annual medical inspection and examination at Framingham, ten thousand out of a population of sixteen thousand have already presented themselves for advice. Sir Arthur Newsholme calls this "a practical and exemplary method of life saving." (*Lancet, ii, 5183, p. 1409, Dec. 30, 1922.*)

The Reorganization of the Federal Health Service

THE creation of a department of public welfare in the Federal Government was perhaps the most outstanding concrete plank in the pre-election platform of President Harding. A tentative attempt was made to carry out this plan by the introduction of two senate bills in 1921 and the whole matter has been re-opened as the result of a conference held in the office of Brigadier-General Sawyer in January, from which there has emanated a new reorganization plan. The present project would create a department of education and welfare, including four bureaus devoted respectively to education, public health, social service, and the work of the present Veterans' Bureau.

The plan for the new department has aroused vigorous opposition in many quarters and appears to lack the active and enthusiastic support of any of the agencies involved. The teaching profession will not be satisfied with anything less than a Secretary of Education and many of the departments affected see a serious menace to their efficiency in the proposed agglomeration. From the health standpoint, while it would be more logical for the Public Health Service to be included in a

department of education and welfare than in the treasury department as is the case under the present organization, this advantage is overbalanced by the very real danger that a reorganization might interfere with the high standards of the present service, which, in defiance of logic, has always received the intelligent support of the various secretaries of the treasury.

There is an old saying that one cannot make an omelet without breaking some eggs, but in the present instance the omelet seems a somewhat unsavory one, and there are some very valuable eggs which we should be sorry to see broken. The counselors sought by the President in regard to this matter have been by no means representative of the public health profession, and it is perhaps this fact above all others which makes one fearful of any plan carried out under such doubtful auspices. The U. S. Public Health Service as it stands today is an organization of which the nation may be proud, ranking with the national health service of any country in the world. Until a reorganization plan is prepared with the co-operation of those who really understand the situation, the representative public health workers of the country, it will be far better to "bear those ills we have than fly to others that we know not of."

Conditions Affecting Child Health in the Sunny South

NO ONE who has recently visited the southern states and studied their health conditions at first hand can doubt that state and local health authorities are now facing peculiarly difficult problems. Of outstanding importance are certain problems of maternity and child health which northern and western sections of the country understand and appreciate but little. It is, of course, generally recognized that the social, economic, and sanitary status of the negro complicates the situation. It is known that the infant mortality and tuberculosis rates among negroes are exceptionally high. It is stated offhand that rickets is very prevalent in negro children, that gastro-intestinal diseases abound; and that syphilis also is thought to be widespread among negroes.

Very few careful studies have been made of negro children in the South to determine just what the conditions really are. Recently a thorough examination was given to about five hundred negro children by physicians¹ in one of the large manufacturing centers in Alabama. The conclusions reached from this study demand earnest consideration. It is stated that (1) "the number of negro mothers unable to nurse their infants is rapidly increasing; (2) malnutrition is universal among artificially fed negro infants," and is quite prevalent among negroes between the first and second year, and common among older negro children. No mention is made in this study of the prevalence of syphilis. We have figures from the Johns Hopkins Maternity Service which reveal a very high percentage of syphilis among the negro mothers coming to that clinic; and the systematic treatment of these mothers with salvarsan has served to reduce materially the number of syphilitic infants.

The congenial environment of the South should contribute to a healthy and happy childhood. The large amount of sunshine, the moderate climate, the abundance of fresh fruits and vegetables (in certain sections) and the outdoor life are all conducive to good health. To offset this, however, the housing in many places is very bad, especially in the rural districts; and crowding in the individual cabins marked. Instead of mothers feeding babies at the breast, as they are undoubtedly capable of doing with proper encouragement, the babies are often put upon patent foods or starchy diets at an early age. By the end of the first year the robust health which they enjoyed during the early months, while on the breast, has been de-

pleted. There is a noticeable lack of good dairy herds throughout large sections of the South and the price of cow's milk is exceptionally high. Here is an opportunity for much educational work. It would be of great economic as well as health value to the South to increase the number of milk cows and encourage the people to use more dairy products.

The midwife situation is notoriously bad. In Louisiana 50 per cent of the births are attended by midwives—of this number, excluding New Orleans, 82 per cent are negroes. Most of these midwives are untrained, ignorant, careless, and filthy; and the results of their work are seen in the increased number of deaths of mothers and of infants in the early months of life. The checking up of all midwives and their careful supervision by the state departments of health would be a highly salutary measure.

The solution of the problems of the South must be sought chiefly by the South itself. There is a very encouraging movement everywhere to correct such unwholesome conditions as have been described. Public opinion in the South is alive to the importance of health and understands that no people can live half healthy and half sick without influence one upon the other. One way to approach the problem would be to secure better training of colored physicians and nurses along maternity and child hygiene lines. The employment of a larger number of trained negro public health nurses would do much to solve some of the rural, as well as the city problems.

One of the fundamental necessities is to encourage the negroes themselves to build better houses and to demand better housing conditions in their rented places. An admirable point of attack would be the training of young men and women in the normal schools and institutes in suitable methods of health education. This could be very easily done by introducing courses in child care through the home economic departments. It has already been demonstrated in several places that under favorable economic and sanitary conditions it is possible to reduce considerably the infant mortality among negroes. One of the largest negro life insurance companies now employing public health nurses in the South states that in their experience mortality among children and adults has decreased notably during recent years.

Problems of malaria and hookworm control will continue for some time to command the attention of health officials in the South. There should be coupled with such sanitary measures a public health service for mothers and children which will assure them a sunny motherhood and childhood.

Old and New Hazards of Water Supply

A RECENT bulletin of the New York State Department of Health reports more than one thousand cases of mild water-borne diseases (to be followed very probably by typhoid fever at a later date) resulting from the action of the water commissioner of the town (a well-known health resort) in drawing an emergency supply under conditions of water shortage from a polluted lake. Such misguided action with its resulting dangers to the health of the community as a whole is familiar enough in the history of public water supplies, but it will be made less frequent in the future if passage is secured for a bill introduced at the instance of the Department into the New York State Legislature, making local health officers ex-officio members of local water boards so that they may be fully informed as to any proposed action in the direction of a change in supply.

The same episode discloses a new hazard relating to water supply sanitation, a hazard involving the health department engineer. In the course of installing an emergency chlorin apparatus the engineer of the state department was badly burned about the face with chlorin gas as a result of a break in a connecting tube of the apparatus. So far as we are aware this is the first case of the kind to be reported but it suggests the desirability of supplying engineers employed in such tasks with a gas mask for use when necessary.

Healthy Skepticism—Dogmas Fall Before Courageous Inquiry

THE sanitarian who thinks for himself, who is unwilling to accept without question dogmas which by reason of age and repetition have secured general belief, who maintains that judicial mental attitude which arraigns the tenets of our sanitary faith before the bar of fact and reason, finds himself in many quandaries.

There is a certain fascination about platitudinous catch-words and it is of course much easier to accept ready-made epidemiological creeds than to sort out the false from the true; but it is only through a thoroughgoing skepticism that sanitary medicine will advance. There is a healthy humility which comes from finding out just what we do not know and in discovering how incomplete is that which we think we know. The courage which is required ruthlessly to drag our cherished doctrines into the pitiless light of day is a builder of scientific character, a stimulant to research, a

creator of a wholesome incredulity which will not accept theories as truths and unproved presumptions as facts.

And this is not remarkable when the history of the evolution of hygiene is considered. Time and again time-honored beliefs which were apparently well proved have been swept aside by the discovery of a simple scientific fact, and on many occasions campaigns for the eradication of a disease have been conducted on lines which seemed justified by the results achieved, later shown to have been entirely incorrect. Even when the first application of a newly found fact is viewed in retrospect, it is usually seen that much unnecessary labor was performed and considerable amounts of public money uselessly expended in doing needless things. There is a constant simplification of the processes of disease control, but it is only by seeking to differentiate accurately between the actual and apparent causes of these results that progress comes.

Our successors are going to be astonished at how well we have managed in the control of diseases about which our knowledge is so pitifully imperfect. We now accomplish results by roundabout methods which they will reach directly. We are still in the blunderbuss stage so far as many diseases are concerned and are obliged to shoot a scatter target in order to hit the bull's eye. They will be able to use a weapon of precision in a greater number of diseases than do we because they will know many things which we do not.

Probably more research has been devoted to tuberculosis than to any other disease of man, yet do we know definitely just how the disease is usually spread, how the causative organism usually enters the body, whether or not its appearance in adults is a recrudescence of childhood infection or a re-infection or an infection *de novo*? We have been taught to consider the fly as dangerous as a cobra but do we know, have we really proved for all time that it does the amount of damage with which it is ordinarily accredited? What do we really know about the causes of the seasonal prevalence of disease, why is one a cold-weather and another a warm-weather infection? Have we determined beyond question the causative micro-organisms of small-pox, chicken-pox, scarlet fever and measles, diseases which in the sum total of their effects are so serious? Do we know what is the exact mechanism of their spread? Can we determine that a given person is immune to any one of them, except small-pox, or can we artificially immunize large groups against them? Do we know certainly that trachoma is an infectious disease? Have we settled forever whether there is a relationship between yellow fever, dengue, and ictero-hemorrhagic fever?

The list of our ignorances and half truths is appalling, yet when we compare these debits with what we have put on the credit side of the ledger of sanitary knowledge in the past half century, we have reason to take hope. We have, so to speak, barely crossed the threshold of understanding and have opened only a few of the closed vaults of knowledge. One by one keys are laboriously being made to open them and each fact secured makes easier the getting of the next. Never will we have them all but by incessant work and the cultivation of a healthy spirit of doubt, the sum total will be augmented and human life and usefulness made more secure. In the meantime we must use stone axes until we get bronze ones and bronze until we discover steel, protecting, prolonging, and upbuilding the existence of man.

Tuberculosis in Cook County

AN ASTONISHING circular letter was sent out under date of March 20, 1923, signed by Mr. Edgar A. Jonas, president of the Board of Directors of the Municipal Tuberculosis Sanatorium of Chicago and addressed to the physicians of the county. "This letter," it is stated, "is to notify you that on and after April 1, 1923, the coroner of Cook County will not permit the Vital Statistics Department of the Health Department to issue burial permits for persons reported as having died of tuberculosis who had not been previously reported as cases of tuberculosis. The Cook County coroner will make a thorough investigation of all such cases, in order to ascertain and establish the cause of death." The declared purpose of this regulation is to secure more general reporting of cases and to prevent physicians from assuming responsibility for cases treated by irregular practitioners up to the period immediately before death. On the other hand, it seems obvious that such a drastic regulation is likely to produce a wholly artificial decline in the recorded death rate from tuberculosis. It is highly desirable that this disease should be detected and reported in its early stages but faulty morbidity statistics will not be remedied by faulty mortality statistics. It has been claimed even in the past that Chicago tuberculosis rates are markedly influenced by the transfer of moribund cases to sanatoriums outside of Cook County. The present regulation will not only stimulate this practice but is likely to lead to the reporting in any cases where the slightest doubt exists of causes other than tuberculosis by both physicians and coroner. Somewhat similar procedures adopted in regard to typhoid fever have in the past aroused grave

suspicion in regard to the vital statistics of Chicago and it is unfortunate that the really admirable program of the Municipal Tuberculosis Sanatorium should be marred by the policy now promulgated.

Cycles of Pandemic Influenza

AN IMPORTANT contribution to the history of pandemic influenza has been made in the study by Eichel¹ of the cycles of this disease as indicated by approximate statistics extending back to the year 1500. Dr. Eichel is one of those who holds to the view that interepidemic influenza is essentially identical with the pandemic disease and he comes to the exceedingly disturbing conclusion that its pandemic cycles are progressively shortening with the passage of the centuries. The five major pandemics are indicated by his analyses beginning respectively in 1557, in 1729, in 1824, and in 1889 and in 1915. The corresponding intervals between these pandemics, it will be noted, are 172, 95, 65 and 26 years respectively. If the tendency to a shortening of the interepidemic period is a continuing one we may well hope that the investigations recently reported from the Rockefeller Institute may open the way to a more effective control of this disease than has been possible in the past.

Health Work of the League of Nations

GRATIFYING progress was manifested at the fifth session of the Health Committee of the League of Nations² held at Geneva early in January. The most important matter discussed was perhaps the interchange of sanitary personnel, the first two courses having been held with great success in Belgium and in Italy during the months of November and December. The development of systematic epidemiological intelligence and international health statistics now, thanks to the generosity of the Rockefeller Foundation, under the direction of Mr. Edgar Sydenstricker, is rapidly going forward. It is interesting to note, too, that the committee has found it possible to further its work of health education and at the same time to aid the Museum of Health at Dresden, which is so much in need of assistance, by purchasing a considerable set of models from this institution.

Another matter of great importance was the report of the Second International Conference on the standardization of sera which was held in Paris in November. This conference has given

2. League of Nations, Health Committee. Minutes of the Fifth Session. Held at Geneva, January 8 to 13, 1923.

us' at last a definitive international standard for dysentery antitoxin, has adopted in principle an international unit for tetanus serum and has provided for a systematic cooperative study of anti-meningococcic sera, anti-pneumococcic sera, antidiphtheritic sera and methods for the diagnosis of syphilis, which promises to prove of the greatest value to laboratory workers all over the world.

It is particularly interesting to note how an interest in the common tasks of science tends to break down unfortunate artificial barriers. Although neither the United States nor Russia are members of the League of Nations, arrangements have been made by which Surgeon General Cumming can sit with the Health Committee of the League in an advisory capacity and the Soviet Commissariat for public health sat with the Health Committee of the League of Nations at its general session and gave invaluable aid in estimating the health situation in eastern Europe.

Mental Hygiene and Accident Prevention

INDUSTRIAL physicians, safety engineers, and personnel workers who have carried engineering revision to the maximum point of development and still find that accidents continue, will welcome a recent book¹ which opens up a whole new field for their consideration. Mr. Boyd Fisher points out that we ought to consider a poorly equipped mind as a misguided machine and adds: "It is time that we took a hint from the progress which has been made in dealing with other forms of social defect and treated accidents not as delinquencies but as forms of mental error." He attempts in this work a preliminary analysis of the psychological factors in industrial accidents and enumerates fifteen such major causes, grouped under the major heads of ignorance, predispositions, inattention, preoccupation, and depression. Particularly suggestive is his development of the idea that lack of interest in the job is a fertile source of accidents, so that anything which helps to build up a positive interest in the work will prove a factor in accident prevention. The part played by external distractions due to physical disorder or lack of effective factory management is wisely stressed and the student of fatigue will find the discussion of this subject highly suggestive. Although it seems unnecessary to quarrel over the question whether anything but "complete exhaustion following exertion when all further normal stimulation is futile" can be called fatigue, the

fatigue recorded in diminished production and increased accident rate toward the end of the shift is something very real even if it can be overcome by appropriate stimulation.

After an exhaustive analysis of the psychological causes of accidents Mr. Fisher discusses accident hygiene, the logical step beyond accident prevention just as in broader community relations personal hygiene has grown out of public sanitation. Intelligent selection of workers including careful tests of sense organs and as much information as possible in regard to general mental equipment is the first avenue of approach toward control. Next, obviously, is the education of the worker and in regard to this point the author emphasizes the need for individual instruction in place of the repetition of slogans which after a time "have no more weight than do the prayers which Mohammedans in India print on long strips of paper and wind up on a wheel in lieu of reciting them."

Finally and most important of all is the question of "personal audit and adjustment," and "a mental post mortem on every accident case that actually occurs."

Mr. Fisher's book is not always easy reading and his classifications as he himself says are tentative. They will no doubt be subject to criticisms from other psychologists and will be substantially revised in the future. The author has, however, as it seems to us, opened up a field of enormous breadth and significance in a way which should prove most stimulating to everyone interested in the problems of industrial health and efficiency.

Improvements Recently Reported in Sludge Handling

THE bane of the sewage works operator is sludge disposal and for many years it has been clear that the vital need in this branch of sanitary science was the need for more economical processes of dewatering sludge. That such improvements will some day be accomplished has seemed reasonably certain and the favorable results reported from Milwaukee encourage us to hope that substantial progress is actually being made. The chemists and engineers in charge of the sewage disposal experiments of that city report that activated sludge can be dewatered by the use of acid heat flotation followed by the use of the Oliver screen with economy and efficiency and these claims will be eagerly examined and tested all over the United States. It is gratifying to see that the fundamental physical-chemical problems underlying sludge dewatering are at last receiving the study which they deserve.

HEALTH IN INDUSTRY

*Problems Concerning Factory Sanitation,
Industrial Medicine, and the Health and
Efficiency of the Industrial Worker*

New Jersey Industrial Safety Museum

**Clearing House for the Standard-
ization of Safety and Sanitation**

BY L. ERSKINE, CURATOR STATE INDUSTRIAL SAFETY MUSEUM, CHIEF OF BUREAU OF INDUSTRIAL STATISTICS, NEW JERSEY DEPARTMENT OF LABOR, JERSEY CITY, N. J.

ON April 21, 1920, Governor Edwards of New Jersey approved "an act to create a state industrial safety under the jurisdiction of the Department of Labor, to further the standardization of safety and economic stability in the manufacturing of the State of New Jersey." This marked the first step in an undertaking that has, in the few years which have since elapsed, undergone a phenomenal development. As an official clearing house for the standardization of accident prevention, fire protection, industrial sanitation, and stabilization of the labor turnover, it stands today as a monument to its originators and developers, and as an example of the aid that a state can render in assisting employers in their compliance with the provisions stipulated in the laws governing factory employment.

By provision of the measure creating it, the museum is required to serve as an official clearing house to coordinate the conservation activities of the Department of Labor, of the compensation, accident, fire, and life insurance companies, and of the public service and railroad carriers operating in the state. While it is, accordingly, primarily concerned with the lessening of industrial injuries, it also covers the field of public and home accidents, and of community hazards. Through the establishment of uniform standards and practices among all agencies which are concern-

ed with the reduction of physical and property waste in New Jersey it has supplanted, by centralization, the needless expense and annoyance arising from the existence of conflicting safety regulations among insurance carriers, rating boards and bureaus of the department.

The Safety Museum is located at 571 Jersey Avenue, Jersey City, in a four story brick and steel building. It contains three large halls devoted to exhibits; offices and conference rooms containing displays of hundreds of photographs of hazardous conditions and safety devices; the Hudson County unit of the Rehabilitation Commission; the Hudson County unit dealing with workmen's compensation; and a public employment office, operating without charge to employer or worker.

The procedure of making the exhibits available and of real benefit to the manufacturers is as follows: The factory inspectors, whose home office is at Trenton, tour the state inspecting all factory buildings that come within the provisions of the statutes. In the survey of some establishments, for example, where there were several unguarded and dangerous pieces of machinery and the washrooms were fitted with antiquated plumbing fixtures that made sanitation impossible, the inspector noting these defects would report the former to the chief of the Bureau of Electrical and Mechanical Equipment, and the latter to

the chief of the Bureau of Hygiene and Sanitation. Each of these bureaus would then issue separate orders, for the correction of the defects, to the official at the factory who was responsible for the improper conditions found to exist. This official is then summoned to the Safety Museum for a conference with the state officials. The dangers of the conditions he has tolerated in his plant are carefully pointed out to him. Then, instead of sending him back to make improvements as he sees fit, he is taken into the exhibit halls and shown the adequate and approved types of guards for the machinery under discussion and modern sanitary equipment of a kind that would change his washrooms from a menace to a positive health asset. After such a demonstration as this is made there is then no excuse if it is found on subsequent inspection of the new installations at the factory that they do not conform to the state regulations. At a conference such as that mentioned above there is an unlimited opportunity for educational work with the employer along many other lines of safety and sanitation. It would be a strange manufacturer who would not be interested enough to spend a little additional time looking at the many exhibits that are on display at the museum. Willingly or unwillingly, intentionally or unintentionally he would get a few new ideas; some stimulation to make his factory a bet-

Shows safety scaffolding used in building operations, with two men at the lever that operates the scaffold. Directly under the scaffold are located a number of pieces of safety equipment.

ter place for the working man; and some idea of the fairness of a policy that demands a change and also shows how the change can be made.

The industrial sanitation exhibit room is wired with six different types of lighting. A switchboard permits ready change from one type to another and a rheostat provides accurate and sensitive control of the intensity. Machinery Hall is equipped with Mazda incandescent and mercury vapor lamps. These industrial lighting units throughout the building demonstrate the practical application of the most modern engineering thought on the subject. They illustrate the most satisfactory and economical methods of providing approved standards of artificial lighting, at once free from objectionable glare and disadvantageous shadows. Various sections of the walls are finished in different colors, permitting a comparison of the auxiliary reflecting service of different colored walls, one color with another and with the contrasting conditions found in industry.

By means of window shades the intensity of natural lighting in the rooms of the museum can be matched to that of any industrial work-room under consideration, and the amount of necessary auxiliary artificial lighting determined. The rooms can be completely darkened for tests of night shift requirements, and by the aid of a photometer, the exact foot-candles required by the lighting code ascertained. The museum's lighting equipment is now one of the most comprehensive in the country.

Nine types of flooring, including various kinds of tile and linoleum composition are employed in the industrial sanitation exhibit hall. A completely equipped model cafeteria sufficient to care for 350 persons; model washroom equipment, including, basins, troughs, lockers, showers and closets; a completely equipped first aid room; and an industrial hospital are some of the other exhibits in this hall. The walls back of each of these displays are painted in colors best adapted for the nature of the work.

The effects of these color schemes can be demonstrated with the aid of the various types of lights and reflectors previously mentioned.

Sixty feet of line shafting in Machinery Hall, in addition to twenty individual motor-driven exhibits, provides facilities for demonstrating approved types of standard safeguards on transmissions apparatus, while a number of metal and wood working machinery units are equipped with point of operation guards. A dust removal system on seven types of wood working machines takes care of the removal of dust and waste material.

An exhibit of standard type steam power equipment, has been prepared under the supervision of the Engineer's License and Steam Boiler Inspection Bureau, that includes among other things a model of a standard type of horizontal fire-tube boiler, a large longitudinal section of the same type, models of proper boiler foundations, portable and steam heating boilers, water gauges, high pressure steam valves, and an improved stop motion on an engine governor. The structural exhibit includes an approved elevator installation, safety scaffolding, ladders, and a portable tower for ceiling repair, the latter fitted with adjusting devices so that it can be used on uneven floors. Space forbids mention of even a small part of the interesting things that one can see at the Safety Museum. Even the sewing machine is there with a properly guarded belt.

The fire prevention display includes, many kinds of fire fighting apparatus, safety storage cans, building material, fire proof windows, doors, and several types of automatic fire alarm signal systems.

On the first floor of the museum is an excellent ventilation exhibit, containing types of sand-blasting rooms and cabinets, exhaust systems for removing dust from machinery used in the manufacture of felt hats, exhaust hoods for grinding and buffing wheels, hoods to remove the fumes from tanks used in electro-plating, and many other pieces of exhaust equipment. When the state orders the installation of an exhaust system for the purpose of minimizing a dust or fume hazard it first shows the manager the proper equipment on his visit to the museum as already described. He is then given specifications for an installation that will be satisfactory to the Department of Labor. These specifications the manager delivers to the contractor that he employs for the work. On its completion the factory

inspectors examine the exhaust system and if it does not comply with the specifications the engineer, very properly, receives no pay for the work. The department not only directs what it wants but it also insures the manufacturer against fraud and aids him in every way to make his factory as safe and hygienic as possible with the knowledge of present day science.

Charts and photographic displays show up-to-date factory buildings erected in New Jersey under the state code, in compliance with the state laws. A valuable collection of photographs, charts, and layouts for practical housing methods in connection with manufacturing plants is available for the employers of the state. The display of structural features arranged by the Bureau of Structural and Fire Protection Inspection will benefit prospective builders of manufacturing plants, as well as those contemplating changes in their present buildings. The bureau is in touch with the leading architects of the different states, and is ready at all times to furnish information regarding proper factory construction and alterations, and the engineer will arrange to go over any preliminary plans at the Museum of Safety before final plans have been drawn.

The stabilizing of the labor turnover by means of betterment provisions, improved employment methods, coordination of the personnel activi-

A general view of one section of Machinery Hall, fourth floor of the museum building. On the right appears a sixty-foot section of line shafting, together with individual belt-driven units safeguarded in accordance with standards of the New Jersey Department of Labor. At the extreme end in the center is a large boiler, weighing eight tons, constructed in accordance with the A. S. of M. E. national code of boiler construction. This room contains twenty-seven motor-driven machine units.

ties, and approved types of safety shop committees are covered by room reserved for the purpose. Group insurance, industrial housing, and community and plant hygiene for the reduction of tuberculosis are also included.

The boiler exhibit in Machinery Hall is used in the practical examination of applicants for engineers' licenses. A museum may mean to some people a place to go on Saturday afternoon for semi-entertainment but the Safety Museum is the home of practical service. There is even an electric floor-scrubbing machine that carries its own water in a tank and rolls around the floor like an overgrown vacuum cleaner.

The photographic exhibits cover many industries that have hazards of various types. Some of the processes covered in the photographic exhibits are laundrying; making of pottery; metal grinding; snuff grinding; printing; and the felt hat industry.

The executive personnel of the Department of Labor of which the museum is a part is under Lewis T. Bryant, Commissioner of Labor, and is composed of: John Roach, deputy commissioner of labor; Charles H. Weeks, deputy commissioner of labor; Rowland H. Leveridge, chief, Bureau of Electrical and Mechanical Equipment; J. F. Scott, chairman, Bureau of Engineers' Licenses; Lillian Erskine, Chief, Bureau of Industrial Statistics; and Wm. E. Stubbs, secretary, Workmen's Compensation Bureau.

The activities of the New Jersey Industrial Safety Museum are under the immediate direction of John Roach,

Shows a solid abrasive wheel used in grinding operations, equipped with a standard type safety hood designed to safeguard the worker in the event of the wheel breaking. On the right a workman rests his hand upon a protective device that guards punch presses. The workman has a long flowing tie that may get caught in the moving parts, which shows that the element of personal care is a matter of serious importance in accident prevention work.

Shows dust and fume removal apparatus used in industry in connection with which the New Jersey Department of Labor has established positive standards of installation and operation. Industrial dust constitutes a menace proved by recent studies to be a more serious affair than mere matters of accident due to unguarded machinery.

Deputy Commissioner of Labor, who has arranged an extensive lecture service on industrial safety including sanitation, accident prevention, the prevention of occupational diseases, and the encouragement of hygienic practices in industry.

This lecture service has required the organization of local Safety Councils in the several industrial areas of the State whose membership is composed of plant engineers, works managers, superintendents and members of safety committees. Safety Councils of this type have been organized in Jersey City, Newark, Camden and Trenton and a regular schedule of lectures on industrial topics has been arranged and carried out. In addition safety meetings are arranged in plants throughout the state and addresses are made to groups of shop employees. Motion pictures are used in all cases in connection with the addresses and it is stated that excellent results have been achieved through the medium of this industrial lecture service.

The Museum is open to the public from 10:30 a. m. to 4:30 p. m., every day in the week except Saturday and Sunday. On the evening of the first and third Fridays of each month an address on safety is given to foremen and safety engineers. This also includes a motion picture.

The fact that the Department of Labor each year serves an average of six thousand orders covering ap-

proximately sixteen thousand items that violate the safety and sanitary conditions of the state is a sufficient reason for the establishment of a museum of this character.

Small Industrial Sewage Treatment Plant

A small industrial sewage treatment plant, constructed for handling the domestic sewage produced by a company at Paterson, N. J., employing a maximum of 420 persons is described in *Municipal and County Engineering* by George L. Robinson. The sewage is purely domestic. There will be no laundries or kitchens and no trade wastes discharging into the sewer.

It is proposed to take the sewage from the building through a six-inch sewer to the treatment plant. This plant consists of the following elements: Gate chamber, settling tanks, and chlorid of lime sterilizing outfit.

The gate chamber is a concrete structure, semicircular in form, provided with two stop planks or gates, set in the invert of the sewer, which will be molded in the concrete floor. These gates are of wood, fitted into a slot moulded in the concrete at right angles to the invert. Easy access to the gates is provided by means of a hinged door in the roof.

The flow of sewage water from the factory may be diverted into either or both units of the settling tanks. When the total population is in the factory each unit is worked six months at a time, the organic matter

standing in one unit and digesting for a period of six months, at which time it can be removed by a hand pump through the cover on the roof. Each tank is 9 ft. long by 6 ft. wide, having a maximum depth of 8 ft. The baffle wall will extend across each tank one foot from the overflow end.

The sterilizing outfit consists of a concrete tank, divided into two parts, each 4 ft. long by 3 ft. wide. The walls are four inches thick, made of concrete mixed with waterproofing. The structure rests on concrete piers, 12x12 inches, at an elevation of three feet above the finished floor. From the bottom of each storage tank extends a brass pipe to an automatic dosing box. This brass pipe is provided with two valves. On the floor in front of the storage tank and directly over the brick well is set an automatic dosing orifice box. A one-inch water pipe is provided to the mixing trough and a piece of hose about two feet long makes it so that water may be distributed into either of the mixing troughs.

The entire structure rests on a concrete floor, and is enclosed in a neat wooden house of suitable dimensions.

The overflow from the settling tank passes through a six inch vitrified pipe and makes connection with the mixing chamber.

Industrial Accidents Tabulated

A convenient compilation of industrial accident statistics has been made by Chaney in the *Monthly Labor Review*, who presents the number of fatal and nonfatal accidents for the various states for the years 1917 to 1921, inclusive. The number of accidents in Pennsylvania are given by industries for the years 1916-1920, number of accidents occurring in Massachusetts during the year ending June 30, 1920, are tabulated by industries and extent of disability and half a dozen of the major industries of the country are then treated in detail.

The total number of fatal and non-fatal accidents as reported by the various states have been as follows:

Year	Fatal	Nonfatal
1917	11,338	1,365,060
1918	12,531	1,345,727
1919	10,806	1,365,520
1920	11,019	1,656,316
1921	9,224	1,317,090

Canada is asking the cooperation of the United States in its drug fight. Officials of the dominion narcotics department will visit Washington for the purpose of formulating some international plan. There are 15,000 known drug addicts in Canada, and evidence of the existence of an international "dope ring" with headquarters in Montreal and operating also in New York and Chicago, has been discovered.

Employees' Attitude Toward Medical Service

By ROBERT E. ANDREWS, M.D., MEDICAL DIRECTOR LUDLOW MANUFACTURING ASSOCIATES, LUDLOW, MASS.

OF ALL the service activities in industrial establishments today, that of the medical department has proved itself the most necessary and important to both employer and employee wherever it has been installed and developed. Medical and surgical work has proved to be the one activity most freely and readily accepted by employees, and against which not even the breath of suspicion of paternalism has been raised.

The physician in industry, through the adaptation of professional service to a special industrial environment, has developed an extremely interesting train of contacts, both with executive procedure, and with the very intimate relations of physician and employee patient.

While many interesting factors have played their part in developing the almost universal support of medical work in industry, that factor of the change of viewpoint toward the work of the physician in industry both by employer and employee is perhaps the most interesting.

In the early development of the medical department in establishments, the idea was not easily sold to the heads of industries. Conservatism fought the initiative of starting a department having no known or tried place in the organization. In addition, there loomed a sizeable overhead for carrying on activity outside of production, which meant spending considerable money, the return for which was intangible and with the further possibility of upsetting existing rules and regulations within the plant. The attitude of their employees loomed large as an uncertain factor which they feared might be antagonistic.

The pioneers who first introduced medical service in industry, held at the start great expectations of positive health, which as the development proceeded, gave way to a realization of its limitations and a recognition of the preventive aspects of the work. It has taken at least ten years even partially to standardize medical and surgical practice and procedure in industry, largely because of the very attitude of mind of the plant executives enumerated above. Step by step, their doubts have proved ungrounded, so that today industry accepts medical service as the most necessary part of service which is established in the plant. Step by step a small outlay

has led to more and more allowance for medical development in every industry that has introduced it, and the ready acceptance of the workers of this branch of service has astonished the heads of many concerns.

It has been scarcely four years since the writer introduced full-time medical service in a large textile industry, but during that time it has been his privilege to observe the changed outlook both of employers and employees toward such service. At the start the proposal to give physical examination to all in-coming employees, met with considerable skepticism on the part of the executive management as to its advisability or

management, it is interesting to note how the employees felt. As was to be expected among unskilled labor, in the majority Polish and Portuguese, there was at first sporadic hesitancy, and here and there a case of mildly passive resistance to examination. The majority, about 75 per cent, were "re-hires," some of them having been re-hired several times over a period of years. The commonest complaint was: "What is the big idea of all this? I've worked here so many years and never had to go through this before. Are they trying to find out something that will keep me from my job."

Here were two problems, unenlightenment and suspicion, which must be immediately and successfully met. The solution was astonishingly simple. Immediate and complete conversion to the idea followed the simple explanation that we wanted to be sure there was nothing in their condition which might hurt them on the job, and that if any physical defects were found, work would be given them where they would not be liable to hurt themselves. Almost invariably the reply was:

"That's a good idea! Why didn't they do this before?"

And right then and there was the psychological moment to explain to them that a physician and nurse were during working hours constantly at their service for consultation and treatment of any conditions that might need attention.

It has been stated that the first impressions are the most lasting, so this first contact with physician and nurse was made as effective as possible through kindly tact and courtesy, in forming in the minds of the prospective employees a favorable impression of the medical service offered them.

If to the many months devoted to special study of industrial medical problems there were added a few more hours of study on the state of mind of sick or injured workers who are about to consult the plant physician, we might hope for fewer occasions of failure. No matter how fine and extensive an equipment, and how elaborate a medical department is built up, if the employees—and they are keen critics—once gain the impression that the physician does not personally throw all his professional interest into their individual case, the medical department is slipping, and slipping

The physician's consulting room where the Ludlow employees are given free diagnosis and advice.

success. It seemed a drastic step, and one that they felt they were not quite ready to undertake and that they felt should not, if tried, be given general publicity among the help until it had been proven acceptable to a considerable number of employees. The argument that it might just as well be tried out then as to wait several months before proving its value, gained assent to its trial with the understanding that nothing be said about it until at least six hundred examinations had been accepted by the help.

After four years of physical examinations of entering employees, this branch of medical activity has proved perhaps the most valuable of all the prevention work developed.

In contrast to the attitude of the

The clinic of the Ludlow Manufacturing Associates has succeeded admirably in inspiring the confidence of the workmen.

badly. The remark that "they wouldn't have that doctor for a sick cat?" has been made on occasion, and it has spelled "FAILURE" in capital letters. We must guard against the possibility of such a mental reaction among the employees.

For the first few months after instituting physical examinations, an annoying condition developed in the experience of the writer. There seemed to be a keen and almost devilish delight on the part of a number of girls, who had been given the limited physical examination, to frighten other girls of their acquaintance, who were about to undergo the mysterious process of a physical rating before starting work. Such remarks as "Oh, you wait till the doctor gets through with you! He won't do a thing to you! Wait till he strips you and lays you out" and other suggestive remarks were planted on fertile soil to develop a crop of absolutely ungrounded fears. So that these new employees appeared positively shaking in their shoes with fear of the great unknown that they expected to pass through in being examined. Just a few kindly words of explanation of the whole idea usually served to quiet everything before proceeding, but the pulse often stayed up as an indication that their nervousness had not entirely disappeared.

This disconcerting and annoying interference introduced in a spirit of fun and suggesting the terrorizing of a neophyte before his initiation, seem-

ed a difficult thing to stop. But as a matter of fact ignoring the practice allowed it to gradually die out. This condition has never reappeared in the writer's experience since physical examinations become a firmly established procedure.

Success in industrial medicine is directly proportionate to our appreciation of the mental state of the sick or injured employee. It is not stating it too strongly when we say that we should treat the head first, then the sick or injured part. Success often lies, not so much in what we do, as in how we do it. For instance to prove the importance of considering the mental state, let us study the train of thought of a sick patient on first consulting the plant physician. A possibly trivial ache or pain while at work becomes through introspection an apparently severe condition. Permission is asked to visit the plant physician. All the way there, the possible seriousness of that pain is mentally augmented, until on appearing before the doctor the sufferer is prepared to be told the worst. Right here, the disregard or ignorance of the mental state of the sufferer could result in a very serious blunder. To a physician not long out of his internship, the evident simplicity and minor seriousness of the case would appeal only as something he could readily relieve. And he is tempted to make light of it in comparison with the many major illnesses which he has been accustomed to study and treat.

The assurance that nothing serious is the matter with the patient is all right in a family of education but among unskilled labor the reaction to such assurance given in an offhand way can be almost fatal to the success of the clinic. The employee returns to work, feeling that the physician does not understand his case and does not know how really serious his condition is. At his work and outside he tells his friends the doctor is no good, etc., thus spreading broadcast the seeds of suspicion and distrust. That these seeds can be developed fast is evidenced by a distinct falling off in the clinic attendance which the physician is unable to comprehend or explain. This is not a theoretical condition of affairs but has actually happened within the writer's observation.

Instead of such a reception, the experienced physician in industry, already aware of the state of mind of a consulting employee, assures the patient that he is showing very good judgment in coming to the medical department early before anything more serious can develop. He follows this up with a painstaking search for any systemic upset as a result of which the employee's mind is much more amenable to the suggestion of a rapid disappearance of symptoms. Where the condition is really trivial, but magnified in the patient's mind, such procedure works like a charm. The worker returns to his job reassured, and feeling way down deep in his mind that this doctor "knows his job" and understands his case.

Similarly, take the case of the injured employee on his way to the clinic for the first dressing. His dominant thought in nine times out of ten is that the machine was to blame for his injury. This is probably a peculiar streak of human nature inherent in all of us to a degree, in an endeavor to persuade ourselves that it is not our own fault when we get hurt, and so we blame the works.

The experienced industrial physician aware of the injured man's line of reasoning, treats the mental state as much as he does the wound. He knows that to argue the cause would be the height of folly in immediately inviting a mental opposition to his personality in his capacity of the plant physician. So he shows a personal interest not in how it happened, so much as in what is the best treatment to command. A courteous interest in the case rapidly dissipates the feeling of "blaming the machine" and creates an interest in what is being done. Not infrequently an x-ray of an injured finger and the showing

of the plate to the patient makes a profound mental impression of how much is being done for him to quicken recovery. This is not unfrequently done in the spirit of treating the head as well as the hand.

Another condition of the patient's mind which is frequently not grasped by the industrial physician is the real feeling behind the title of "Doc" with which we are frequently greeted by employees. We as physicians are prone to resent the term as showing a familiarity and lack of respect out of all proportions with the dignity of the profession. But in industry it stands for a real friendliness and state of mind which means trust in your judgment and in your real regard for the workers' interests.

It is a singular paradox that a very evident modesty among young women before the plant physician is strongest in those least modest in their general behavior.

As a case in point, a physically attractive girl of seventeen years, sustained at her work an abrasion just above the left knee. She firmly refused to allow the plant physician to dress the wound. The nurse who was assisting remarked, after attending the injury, on her seeming modesty. Subsequent history showed that she had been threatened with arrest twice within six months for her relations with young men.

Another case was that of modest-appearing girl who consulted the physician at the plant for a pain in the chest. Yet she positively refused heart and lung examination. She seemed embarrassed and the nurse was unable to persuade her to have her chest examined. Here was another case of seeming modesty, where a further history told of frequently wild night life parties in camp and an illegitimate child.

It has been the writer's experience that downcast eyes and modest tendency to blush means that the whole story has not been told; that they beat about the bush in telling their story usually means that they find difficulty in expressing the object of their visit. They will claim to the plant physician to be suffering from a headache, when in reality they visit him for relief of the cramps of dysmenorrhea.

One learns after considerable experience how much further to extend inquiries as to the upset that brings them to the clinic. An experience of the writer was illuminating. One of the girls, believing herself pregnant, came for advice. Apparently when she had the chance to tell of her trouble, she lost her courage, for her

fictitious symptoms had no bearing on her real condition, and as I learned later, the reason she did not tell me was "I didn't ask her" if she was in a "family way." Since then, it is needless to say, the question has been tactfully put in all suspected cases.

Once the real story is told the sense of relief becomes immediately apparent. The false modesty is transformed on the spot to direct gaze and truthful frankness with an expression of countenance that fairly beams with welcome relief.

A probable explanation of the condition of mind shown in many of these young women is the desire to keep inviolate from medical records in industry any reference to their history outside of their work.

There is another class of employees both men and women, but with the women in the vast majority, who ex-

hibit extreme modesty when abdominal examination is proposed. It is almost a safe bet that these cases fear to expose a bad tear in the undershirt or an unbaded body. Modesty in such a cause is by no means confined to industry.

The successful plant physician has developed a position where he must withstand the criticism and mould the judgment of a group of exceptionally keen employee-critics. His personality is compared by them with that of the local general practitioners and must not suffer in the comparison. Success lies not so much in what he does, as how he does it. But to hold this success he must strictly adhere to the policy of unbiased consideration of the employee patient in the light of a private patient, whose personal interest overshadow any employee relationships to the industry.

Recent Compensation Decisions

BY DOROTHY KETCHAM, ANN ARBOR, MICH.

THE constitutionality of a statute requiring certain establishments to maintain wash rooms was tested in action brought against a railway company for failure to make such provision. Such a one of this act (Laws of 1913, page 359) is as follows:

Section 1. That every owner or operator of a coal mine, steel mill, foundry, machine shop, or other like business in which employees become covered with grease, smoke, dust, grime, and perspiration to such extent that to remain in such condition after leaving their work without washing and cleansing their bodies and changing their clothing will endanger their health or make their condition offensive to the public, shall provide and maintain a suitable and sanitary wash room at a convenient place in or adjacent to such mine, mill, foundry, shop, or other place of employment for the use of such employees.

The defendant was found guilty and fined. It then brought *certiorari* to the Supreme Court on the grounds that the act was unconstitutional and that it did not apply to railroad roundhouses. The constitutionality of the act was upheld but its application to roundhouses such as defendant's was denied and the judgment was reversed. The decision in part is as follows:

The purpose of the act as declared by the title is to protect the health

of employees and secure the public comfort, and it was enacted under the police power, with suitable provisions against liability to disease or offense to those with whom the employees come in contact after leaving their places of employment. The act applies to all places of employment where the prescribed conditions exist, and as a police regulation and applied to such conditions it is constitutional and valid. (*People v. Solomon*, 265, Ill. 28, 106 N. 458, Bul. No. 169, p. 115.) The conditions so prescribed are that the employment is one in which employees become covered with grease, smoke, grime and perspiration to such an extent that to remain in such condition after leaving their work without washing and cleansing their bodies and changing their clothing will endanger their health or their condition be offensive to the public. If the evidence showed that these conditions existed in the place of employment provided and maintained by the plaintiff in error, the judgment was right; if it did not, the judgment was wrong.

The act does not apply to every place of employment in which men become dirty or perspire, but only to those where they become covered with grease, smoke, dust, grime and perspiration to the extent specified in the act. In warm weather all persons perspire, whether at work or play, and there are numerous kinds of employment in which the employees get grease on their clothing or become dirty with smoke or dust, but not to the extent specified in the act. Neither their health nor the public comfort is involved. That is

true of the ordinary blacksmith shop, the garage, or the supply house for farm machinery. There was no justifiable inference to be drawn from the evidence that the employees of the plaintiff in error were in such a condition after leaving their work that without washing and cleansing their bodies and changing their clothing their health would be endangered or their condition be offensive to the public. This is not saying that there must be opinion or expert evidence of such probable consequences, nor that a jury may not determine that question from the facts proved in the light of common experience, but the evidence did not bring the roundhouse and machine shop within the terms of the statute.—*People v. Cleveland, C.C. & St. L. Ry. Co., 123 N.E. 579.*

IF THE death of an employee is fairly chargeable to an accident suffered in the course of his employment, the Supreme Court of Illinois, June 21, 1922 has declared that compensation may be awarded even if there is a pre-existing disease aggravated or accelerated by the accidental injury. There must, however, be a direct relation between the death and the consequent disability or death.

In the case at hand an employee died of pneumonia which set in four days after he had sprained his back. The only evidence of accidental injury as the cause of death was the testimony of the attendant physician. The opinion of the doctor was, "both at the time when he treated him and at the time of the hearing that there was no connection whatever between the sprain at the back and the death." "The most that the doctor was willing to say was that there was a possibility, due to the weakened condition of Zara from pre-existing disease and increased weakness from the sprain, that the sprain may have been the predisposing cause of pneumonia; but in his opinion there was no connection whatever. There was an entire failure to prove that the death of Zara was due to an accidental injury suffered in the course of his employment by the plaintiff in error."—*Springfield District Coal Mining Co. v. Industrial Commission, 135 N.E. 789.*

INSANITY which resulted from a cerebral hemorrhage was held compensable as an accidental injury within the Workmen's Compensation Act by the Supreme Court of Illinois, June 21, 1922.

An iron molder, twelve years an employee and steady worker of the Jenes Company, had been addicted to

the excessive use of liquor and had had delirium tremens. He was afflicted with arterio-sclerosis and had a high blood pressure. He worked in a foundry carrying molten metal and pouring it into flasks. The temperature of the room was about eighty degrees although the weather outside was colder. About the middle of the afternoon, the employee "who had been engaged two or three minutes before in the work—was seen leaning against a flask, and a few of the workmen were talking to him but he did not answer." A doctor was called, the man was taken to a hospital, and later taken to Dunning. After a hearing the arbitrator awarded compensation which was affirmed by the Cook County Circuit Court. The employer sued out a writ of error to reverse the judgment on the ground that "the record contains no evidence of any ac-

cident arising out of and in the course of employment."

In the opinion of the Court, the employee "was overcome while he was at work, under circumstances which furnish an adequate cause for the result. . . . He might have suffered this stroke in the same way if he had stayed at home and not worked that day, but he did not, and he did suffer his stroke as the combined result of his disease and his work. The rupture in the blood vessel in the brain was an accidental injury, and although his existing disease predisposed him to an accident of this character, we have held that death under such circumstances may be said to have resulted from an accidental injury and is the proper basis for an award of compensation."—*W. A. Jenes Foundry & Machine Co. v. Industrial Commission, 135 N.E. 754.*

Physicians in Industry

IN THE discussion of the economic value of medical departments in industry, it was pointed out at the thirty-seventh meeting of the Conference Board of Physicians in Industry that the medical department of one of its members had saved his organization more than \$69,000 in 1920. If this company had been operating under the state insurance plan, which in this case was an exclusive state fund, the premium would have been more than \$69,000 above the cost of operating the medical department and the payment of such compensation as was necessary. The company was self-insured and through the medical department was able to pursue other activities of benefit to the workers, which would not have been possible under any other form of insurance.

In discussing methods of resuscitation from carbon monoxid poisoning, the use of oxygen alone and combined with carbon dioxide was discussed and the experimental work which has so far been done along this line was reviewed. It was the consensus of opinion of the Conference that no form of mechanical inhaler should be operated by an untrained layman, and that the use of these appliances should be restricted to those who have received special instruction in their construction and operation. For general resuscitation the Conference reaffirmed its endorsement of the prone pressure method over all others.

In discussing injuries to the lower back, the importance of considering the fifth lumbar vertebra was empha-

sized. This vertebra is the most important of all the spinal segments as it is the last mobile segment above the sacrum and as such bears the greatest weight due to body movement. It is also the one most frequently fractured. Anatomical abnormalities of this segment, such as elongated transverse processes, malposition of the facets and undeveloped pedicles together with elongated spinous processes may be present. If the elongated transverse processes rest upon the crest of the ilium they are likely to produce pain. The variation in the lumbo-sacral angle is also of importance when these processes are of abnormal length.

Malposition of the facets may cause a twisting of the vertebra, thus producing a strain. Contact between the elongated spinous processes of the fifth lumbar and the first sacral may also be the cause of discomfort.

In early life before ossification is complete the spinal column is more mobile and may maintain its anatomical balance without producing symptoms but if after complete ossification an injury occurs which disturbs this balance, it would be impossible for the patient to obtain a readjustment and pain and disability will result.

Ununited fractures of the laminae following injury many times are the cause of disability, and failure of fusion of the first sacral arch, causing a partial spina bifida, has also been encountered as one of the abnormalities that cause trouble later in life.

The Care of the Injured Miner*

BY R. R. SAYERS, CHIEF SURGEON, U. S. BUREAU OF MINES, SURGEON, U. S. PUBLIC HEALTH SERVICE.

THE care of the injured miner has many phases, each of which must be emphasized if the best results are to be realized. These phases are well known—the prevention or elimination of accidents and health hazards, the first aid and emergency treatment, and the medical and surgical care. The first two are by far the most important, as much more good can be accomplished with an equal expenditure of effort. Therefore only these two will be discussed.

Methods for prevention or elimination of hazards in the mineral industries are studied by the United States Bureau of Mines, the first aid methods for treating injuries developed and taught to the workers.

To aid in the elimination of accident and health hazards, their prevalence in the mineral industries is determined by collecting statistics. After the statistics have been compiled, analyzed, and interpreted, investigations are made in the mines as to the causes of the more important hazards and the best practical means to eliminate them are determined as far as possible. Finally, the information obtained is given to the mining public to be used to care for the miner before injury by eliminating and minimizing the hazards and immediately after injury by giving first aid or emergency treatment.

As an illustration, statistics showed that the death rate due to tuberculosis was unusually high in certain mining districts in South Africa, as on the Rand, and in sections of this country, as Joplin, Missouri, Butte, Montana, and others. Based on these statistics, many long and careful investigations were made. The studies included the making of physical examinations of many miners; laboratory examinations of the sputum; x-ray examination of the chests; examination of necropsy specimens, when available; and chemical and petrographic examination of dust breathed. These studies showed that miners who breathed rock dust while at work developed pneumoconiosis or silicosis, especially when the dust was highly silicious and was needlelike or had sharp cutting edges. Severe cases caused marked difficulty in breathing to a point where little or no work could be done, even without bacterial

lung infection of any kind. It was found, however, that silicosis made the miners very much more susceptible to tuberculosis when exposed to the infection. The preventive measures were obvious: (1) To prevent the breathing of dust, by use of wet mining methods, and by good ventilation to replace the dusty air with clean air; (2) to make physical examination of all miners on application for employment and at regular intervals thereafter and to allow underground in these mines no miner found to be infected with tubercle bacilli. This is for the good of the infected miner and for the protection of the healthy ones with whom he would work.

Other health hazards of the industry, as lead poisoning, mercury poisoning, carbon monoxid poisoning, and poor sanitary conditions have been studied and recommendations made for their improvement or elimination.

In some districts more than 25 per cent of all deaths among coal miners are due to accidents, and statistics show that about 50 per cent of the fatal accidents are due to falls of rock or coal. Of 1,973 fatalities in coal mines during the year 1921, 1,019 were due to falls of rock, coal, etc. The causes of these accidents are carefully investigated and may be attributed to (1) poor inspection by inspectors, bosses, and miners; (2) not properly barring down loose rock when found; (3) improper or insufficient timbering.

The miner can do much to prevent these accidents by carefully inspecting his working place, barring down the loose rock and properly timbering. Lack of knowledge of the causes and avoidance of these accidents may be responsible for some of them but carelessness and chance-taking are responsible for the great majority. Most miners know the dangers and also know the precautions they should take to protect themselves but are, like all men, chance-takers and careless. If properly to bar down the loose rock and properly timber the working place means delay, they take a chance.

After an accident the care of the injured man is of immediate importance. This care may be emergency treatment by a physician or first-aid care. First aid is the temporary care of an injured person by simple common-sense methods, based on principles of medicine and surgery, which may easily be applied by a layman.

The principles upon which first aid are based are:

(1) Asepsis in caring for all open wounds, using Bureau of Mines methods. The first aid men are instructed not to touch or put anything on open wounds except a dry sterile dressing. A bandage compress, which consists of several thicknesses of sterile gauze sewed to the middle of a strip of muslin, is used to cover all open wounds. Three sizes are used—large, medium, and small. The bandage compress

Three man lift—the proper method of lifting an injured man.

*Printed by permission of the Director of the U. S. Bureau of Mines.

Artificial respiration—prone pressure (Schaefer) method.

should usually be covered by a protective dressing. The triangular bandage has been found very suitable for this purpose as it can be adapted to cover any part of the body. The triangular bandage is used either in the open form or folded cravat. In addition to being used to protect the other dressings, it may be used as an improvised tourniquet and to hold splints in place, etc. A triangular bandage may be made from any kind of cloth such as a handkerchief, piece of shirt, or napkin. It has been found, however, that a triangular bandage made from a piece of muslin forty inches square by folding the square diagonally and cutting across the long side, making two triangular bandages, is most satisfactory.

(2) Control of hemorrhage by means of pressure and position of part. The pressure may be direct and remote in arterial hemorrhage. In the latter type of hemorrhage a tourniquet, which may be improvised, is applied to a point (known as pressure point) between the wound and the heart where the artery is superficial and a bone is directly under it.

(3) Shock is treated by keeping the patient lying down at rest; keeping him warm by covering him with blankets or clothing, using hot water bottles, hot bricks, warm safety lamps, etc., aiding circulation by rubbing the extremities towards the heart but not away from it; by use of common stimulants, as hot coffee or aromatic spirits of ammonia.

(4) Asphyxia, electric shock, and apparent drowning are treated immediately after rescue, by artificial respiration, using either the Sylvester or Schaefer method, although the latter is preferable as it is simpler and not so tiring. If the subject has been exposed to carbon monoxid, he should be caused to breathe pure oxygen as

the recovery is much more rapid. The oxygen should be given as early as possible after rescue.

(5) Burns are treated, after removal of clothing, by application of sterile picric acid gauze, aseptic precautions being observed as in open wounds. The picric acid has styptic, antiseptic, and some anesthetic properties. Picric acid gauze dressings are covered with triangular bandages which hold the dressings in place and exclude the air.

(6) Dislocations and fractures are treated by immobilization in a comfortable position, and a natural one if practicable, care being taken not to move the injured part unnecessarily. Well-padded splints are held in place by cravat bandages.

(7) Transportation may be necessary to get an injured man to a place of safety, or one more comfortable, and to get him to a hospital and physician. The methods vary with conditions but the principle of transporting him so that he will suffer no further injury is emphasized whether he is transported on a stretcher or by one, two, three or more men.

Knowledge of first aid has been found materially to lower the lost-time accidents where a sufficient number of the miners are trained. This is due to the early care preventing minor injuries from becoming serious and by the fact that men trained in first aid are more careful men. Recently all the employees of one company, which employs over four hundred men, were trained in first aid. Their records show that their lost-time accidents decreased 50 per cent for a six months' period after the completion of the training. Insurance companies recognize the above facts and allow a lower rate of insurance where a certain percentage of the workmen are trained.

Summary

The care of the injured miner includes:

(A) Prevention and elimination of accidents and health hazards by (1) A study of statistics, (2) Investigations of accidents and conditions, (3) Education and legislation.

(B) First aid care.

(1) Principles of first aid, (a) Asepsis in caring for open wounds. (b) Control of hemorrhage by pressure and position of injured part. (c) Treatment of shock by keeping patient at rest and warm and by giving simple stimulants. (d) Artificial respiration in asphyxia, electric shock, etc., combined with use of pure oxygen in carbon monoxid cases. (e) Asepsis in treatment of burns; protection from air if this can be done with asceptic method; antiseptics and some relief of pain by use of picric acid gauze. (f) Immobilization of dislocations and fractures. (g) Transportation by methods which will not increase the extent of injury.

(2) In addition to the benefits gained by early care of the injured, first aid has been found to tend to lower accidents by making men more careful.

An Industrial Campaign Against Venereal Diseases

An industrial campaign against venereal diseases has been carried on in Florida among the employees of two great railways, the Atlantic Coast Line and the Florida East Coast. American Social Hygiene exhibits were utilized, and nineteen illustrated lectures were given under the joint auspices of the Florida State Board of Health and the United States Public Health Service. More than 5,850 railway employees were reached in the campaign.

Turkey Enacts Laws for Benefit of Laboring Classes

Turkey has recently enacted her first legislation for improving the conditions affecting the working people. Fifteen thousand coal miners in one of the mining districts will benefit by these laws, which provide that mine owners must construct for their workmen houses of concrete, stone, or brick, with wooden floors, and an adequate number of windows. A public bath, a mosque, and evening schools must be established in each mining district, and the law requires that a pension fund be created for injured and aged employees.

Industrial Hygiene in Saxony*

FOR centuries the freestate of Saxony has been one of the most densely populated sections of Germany. The rapid increase in the population in the mountainous districts was at first due to mining. After the mines were exhausted, the nature of the soil not being suited to agriculture, the majority of the inhabitants were forced into industrial pursuits. "As early as 1849 the number of industrially employed in Saxony was larger (45.3 per cent) on an average than in the entire German empire in 1907 (37.2 per cent). In 1907 the number of inhabitants employed in agriculture amounted to only a trifle over one-tenth of the population. There are more medium size factories of 11 to 50 workmen, (in 1920 over 90 per cent of all factories and their kindred industries) in Saxony, than in the remainder of the German empire.

At the last industrial census (1907) Saxony averaged of all workers employed in Germany, textile industries 30.2 per cent, in paper industries 20.9 per cent, 17.9 per cent in miscellaneous industries, 12 per cent in clothing industry, and 11.9 per cent in the industries of machinery, instruments and apparatus. These are the most important branches of industry. The last workmen's census of May 2, 1921, cannot be considered an accurate outline of the working year on account of the political and economic conditions; but it indicates that of the factory workers of Saxony, 26 per cent are employed in textile trades, 22 per cent in machine and instrument making, 9 per cent in metal working, 7 per cent each in shoe and clothing industries, 6 per cent each in wood working and in paper making, 5 per cent in stone and earthenware work. More than half the workers in textiles and clothing industries are women as are about 40 per cent of the workers in food industries and paper making. Over 10 per cent of the workers in machine and instrument making, in metal work and clothing are children, as are about 9 per cent of those engaged in food industries and wood working.

In Saxony there is also a great deal of home industry, constituting main vocation as well as bywork or extra means of support. In 1907 home industry in Saxony amounted to one-third of all the empire, and this in

turn was one-third of all investigated industries. The chief branches of home industry in Saxony are certain specialties in the spinning industry, (machine and hand knitting, weaving, reeling, repairing, knitting, etc.), also the manufacture of artificial flowers, textile and leather gloves, musical instruments, wooden toys, furniture, splint baskets, straw hat braiding, brushes and cigars.

Following Bavaria's example, a medical director was appointed October 1, 1919, in the national department of industry. His field of operation consists of: (1) Cooperating (a) with the department of industry and by request with other departments; (b) with supervisors of industry, mine inspectors, regarding questions of industrial hygiene and enforcement of the workman's protection law, inclusive of home-work law, especially in vocational diseases, factory hygiene (dressing, wash and bathroom arrangements, toilets, airing and keeping clean), employment of female and juvenile workers, questions of fatigue as well as unsanitary condition of water, air and floors and annoyance caused by noisy machinery.

(2) Supervision of statistics of sickness and death of vocational workers, general examinations in single vo-

cational branches, if necessary, experimental laboratory work, lectures, educational courses, consideration of the different social hygienic problems and questions of choice of vocation.

The national industrial physician is industrial inspector in the sense of paragraph 139b of the industrial ordinance and possesses the same privilege as the other industrial inspection officers, to inspect industrial plants, but dares not divulge any business secrets that may come to his knowledge during such inspection. He confers with the physicians and officers as well as the physicians of the sick fund, investigates their reports concerning vocational sicknesses and gives his opinion whether the working conditions are unhygienic and whether changes or substitutions are advisable. He is a regular member of the national board of hygiene as well as a member of the committee of the national welfare board, the national committee for vocational advice, and teacher's employment board, the national board of workmen's employment and national board for providing for injured soldiers.

Saxony has, herewith, taken the first fundamental steps toward effecting industrial hygiene through organization of labor.

Serum Institute in Copenhagen

The director of the Institute, Dr. Thorvald Madsen, is the Chairman of the Health Section of the League of Nations and the Institute will serve as headquarters for the cooperative study of sera and vaccines now being carried on by the Health Section of the League

*Translated from *Einrichtungen auf dem Gebiete der Volksgesundheitsund Volkswohlfahrtspflege im Freistaat Sachsen. 1922. Dresden.*

Industrial Psychiatry

WHAT is the outlook for industrial psychiatry? Are the activities of industrial psychiatry to be confined to a mere recording of symptoms, and its benefits to be only the detection and removal of the occasional institutional cases from the ranks of the industrial personnel?

Without attempting to define industrial psychiatry, Dr. Jau Don Ball in the *American Journal of Psychiatry* clearly points the future for the psychiatrist in industry. Industrial psychiatry should not be considered a "weeding out" process, but a method of conservation. The psychiatrist who is to enter the industrial field, therefore, needs to widen his range of vision by a full consideration of industrial environment and wage schedules.

Psychiatry is no panacea for the ills of industry, but it offers the only means of solving industrial personnel problems. Mechanical devices and machinery have had the attention of the engineering groups, but for the most part the worker, under unstudied conditions, and often under undue physical and mental stress, has been permitted to become hypersensitive and abnormal in reaction. As the employer is usually as blind to the situation as the employee, the duty of the psychiatrist is to seek a comprehension of the situation from a psychiatric viewpoint. This is not a philanthropic move in industry, but an advance business method, a method which applies to the whole personnel, from executive to roustabout.

The organization and function of the personnel department, therefore, must be effected by the psychiatrist as director of the department. He should have available consultants in neurology, psychology, and medicine. A special secretary may be needed, and the personnel work should be fully coordinated with the departments of engineering and employment management.

The psychiatrist will be especially concerned in group and individual tests, in work and job analysis, in studies of terminations, distribution of labor, and in the observation of special "situations."

Dr. Ball advocates for all employees a scoring method after the United States Army plan for rating officers, the score for each individual based upon ten qualifications: (1) At least average intelligence; (2) good

physical condition; (3) good nervous condition, to be determined by neurological examination; (4) good mental condition, to be determined by psychiatric examination; (5) personality characteristics of special kind; (6) speed; (7) accuracy; (8) good reasoning ability; (9) good auditory memory; and (10) good visual memory. The score for each person is the total number of points obtained. This is not a percentage score but is based upon qualities or groups of qualities whose values are determined on the basis of the job requirements.

A series of typical cases is given, showing the method of recording together with the recommendations either as to placement or as to hygiene, mental or physical. Another series of cases is reported to show the value of such studies as applied to studies in job terminations. The figures given on terminations constitute an actual study made from one of

the departments of a large manufacturing plant in San Francisco where in a three months period the lack of diplomacy on the part of a single foreman cost the firm in avoidable labor turnover nearly eight thousand dollars.

The work reported by Dr. Ball is the result of three years study of industrial problems in the respective plants of a shipbuilding corporation, a calculating machine manufacturing company, a large soap manufacturing company, and a large oil company. He concludes from these studies that: (1) Every large industrial organization should have a psychiatrist on its staff. (2) Groups of small industrial organizations should seek the services of a consulting industrial psychiatrist. (3) Labor unions should welcome the advice and guidance of an industrial psychiatrist. (4) Every university should establish a department of industrial psychiatry. (5) Personnel departments should be under the directorship of industrial psychiatrists.

Women Workers in Maryland

A REPORT on "Women in Maryland Industries, A study of hours and working conditions," (*Women's Bureau, Bull. No. 24, U. S. Department of Labor*) by Mary V. Robinson of the Women's Bureau describes the conditions found as a result of a study undertaken at the invitation of the Governor of the State of Maryland. In all, 240 establishments were visited, 142 of these being in Baltimore and the remainder in fourteen smaller cities of the state. The establishments divided themselves into four groups, manufacturing, mercantile, laundries, and restaurants. In Baltimore over seventeen types of establishments were visited, while in the remainder of the state more than ten types were treated in a similar manner. Definite information concerning the number of employees and hours of labor was obtained from the employers, while the working conditions were determined by plant inspections. Additional facts regarding personal histories was obtained by the use of cards filled out by the employees.

Broadly speaking, it may be said that this study revealed the fact that in a group of industries employing some twenty-seven thousand persons, approximately half of whom were females, little or no general systematic attempts were made to provide satis-

factory working conditions. This is evidenced by the fact that a large proportion of the plants were needlessly deficient in attention to the physical surroundings of the workers. As examples, it may be pointed out that crowding of persons and machines was manifest in 54 workrooms, cleaning unsatisfactory in 116 workrooms, lighting inadequate in 210, and ventilation poor in 52 workrooms, while obvious fire hazards existed in 148 plants. The sanitary facilities of the plants visited were found to be wholly inadequate, the drinking facilities being so in 172 plants, the washing facilities likewise in 208 plants, and the toilet facilities in 213 plants. In addition to this the survey disclosed the fact that occupational hazards existed in some 97 plants.

In considering the hours of labor it is to be pointed out, as this report does, that Maryland is in general a ten-hour day and 60-hour week state.

This report is very valuable in picturing a cross section of the conditions in Maryland industries, but it is to be regretted that more detailed information concerning such subjects as lighting and ventilation, which are undoubtedly dealt with in only a superficial manner was not secured so that proper provision might have been made in the new labor statutes which it is hoped will soon be forthcoming.

Packing House Waste Disposal

A COURT order made it imperative early in 1921 that Joseph E. Decker and Sons, packers at Mason City, Ia., build with the utmost speed a plant for the disposal of their packing house waste. The wastes of the plant were then being emptied into Lime Creek on which Mason City is located. The city sewage treatment plant consists of Imhoff tanks and trickling filters but was not of a capacity to take care of the additional waste of the packing house. This waste is from water used in washing in the various processes and contains blood, manure, grease, hair, pieces of flesh and other organic matter. It is highly putrescible and though at times of high water, Lime Creek is capable of taking care of screened sewage, in the low water stages, during the greater part of the year, it will not care for the soluble organic matter.

The ruling of the court had left no time for experimental work either to determine the flow or concentrations of the waste. From the conclusions drawn from the experiments at the Chicago stock yards it was decided to build an activated sludge plant. Recommendations included an aeration unit 48 feet long, 39 feet wide and 15 feet deep which would give about eight hours detention with 600,000 gallons flow daily, and a 25 per cent sludge return, a second or even a third unit to be constructed if experience proved that one was inadequate.

Screens and surface tanks had previously been in use at the plant but they had not given satisfaction so that it was decided to abandon them and build a new so-called grease tank

in the aerating chamber of the activated sludge plant.

All waste from the plant is brought to a sump from which centrifugal pumps force it to the grease tank, which is six feet wide at the surface, four feet deep at the shallow side and sloping to eight feet on the deeper side. From the deep side openings controlled by valves lead to a sump from which the sludge can be forced by compressed air to the by-products house.

From the grease tank the waste passes to the aeration chamber, traversing the length of this (48 feet) four times after being mixed with the activated sludge. "The air is blown into the mixture through filter plates placed at right angles to the line of flow in rows six feet apart so that the plates cover about one-fifth of the area of the tank. The space between the plates is elevated so that the settling sludge will fall to the bottom above the plates, and be carried to the surface by the air. The aerating chamber has a capacity of approximately 155,000 gallons so that with a flow of 300,000 gallons with 30 per cent sludge returned, there will be a detention period of about 9 hours."

From the aerating tank the waste passes to a Dorr thickener. This is 36 feet in diameter and fourteen feet deep, contains the regular Dorr mechanism and is constructed of reinforced concrete. The bottom slopes slightly toward the center from which the sludge flows by gravity to an air lift well from which it is pumped to the mixing box at the end of the

grease tanks. "The effluent flows from the rim of the tank which has one-fourth of its circumference depressed. The depressions were made by placing 2x4's every 16 inches in the frame into which the soft concrete was poured. The distribution of the flow is very satisfactory, more so than when an attempt is made to use the entire circumference for overflow."

This plant was put in operation in October, 1921, and a satisfactory effluent developed in ten days. Some trouble was experienced after a Sunday shut down owing probably to the large settling capacity. This was remedied by returning the sludge at the same rate during the shut down as during maximum operation. It is probable that the addition of sufficient water to form a current through the settling basin would prevent putrefaction during a shut down.

It is proposed to treat the sludge with sulphuric acid, draw off the clear liquid, pump the sludge to the by-products house and concentrate the sludge with the tankage. When this plant was described by Edward Barstow (Proceedings of the 34th Annual Meeting Iowa Engineering Society, Sioux City, Iowa, Jan. 17-20, 1922) some sludge had been pooled as the sludge pump was not then installed. During the first winter of operation either because of an overload due to the extra large number of hogs killed or because of the cold weather the plant did not give satisfaction. During the latter half of March good results were again obtained.

Sanitary Surveys of Mining Camps

Sanitary surveys of the mining camps in Utah, Nevada, California, Arizona, and the states of the Lake Superior Districts, are being continued by the United States Bureau of Mines, with the object of determining, insofar as possible, the effect of sanitary environment upon the health of the miner. Reports based on these surveys, calling attention to the especially good sanitary conditions and to the insanitary conditions, will be written from time to time with recommendations for the improvement of the latter. These reports as completed, together with ratings based upon carefully determined weights or values for the various factors which affect the health in the mining camps and communities surveyed, will be forwarded to the operators and others vitally concerned.

Waste disposal plant of a packing house plant at Mason City, Ia., of which the aerating capacity is 155,000 gallons. With a flow of 300,000 gallons with 30 per cent sludge returned, there is a detention period of about nine hours.

Garment Trade Fire Hazards

THE Twelfth Annual Report of the Joint Board of Sanitary Control in the Cloak, Suit, Skirt, Dress, and Waist Industries deal in considerable detail with a survey of 1,168 New York buildings in which shops of the garment trade are located. George M. Price, M.D., is the director of the Board of Sanitary Control. The recommendations for changes in the fire laws and other suggestions are submitted by Rudolph P. Miller, C.E.

It is recommended that buildings erected before October 1, 1913, and not previously used as factory buildings should not be allowed to be used for factory purposes unless they are made to conform with the requirements for new buildings; that all interior stairways in buildings over one story in height should be inclosed; and that access to the roof should be provided even where there is not safe egress from the roof to adjoining buildings.

There exist on many of the old buildings fire escapes which do not conform to the present day requirements. The owners often think that by allowing them to remain they provide added protection. If this is to be permitted they should be structurally safe and provided with drop stairs at the bottom. The owners of buildings equipped with fire alarm systems, according to law, have often let the systems deteriorate or deliberately put them out of commission because approved automatic sprinkler systems were later installed which exempted the owners from maintaining an alarm system. "Whether a building is equipped with sprinklers or not, it is desirable that the occupants of a building should be notified promptly of the existence of a fire by an alarm of some kind."

That provision of the labor law which required the posting of notices specifying the number of persons that may occupy the several floors or spaces in a building is becoming a dead letter. Mr. Miller considers this too important a requirement to be disregarded and recommends a more direct and specific wording of that section of the law dealing with this requirement.

It also appears from the survey that on many buildings the counter-balanced stairs from the lowest balcony of the fire escape were in an unsafe or inoperative condition. In some cases balanced drop ladders were provided in place of the counterbalanced

stair required by the law. It would seem that in this case, since the law is not at fault, that an intensive inspection of fire exits should be made under the direction of the fire commissioner.

It is stated that the administrative authorities are making a serious effort to secure compliance with the law, and that on the whole they are succeeding fairly well. In some cases it is thought that the administrative officials should have the authority to use drastic measures. It is recommended that there be incorporated in the law a provision whereby the fire commissioner in the city of New York, and elsewhere the industrial commissioner, if the party responsible for an unsafe condition fails to correct this condition after being warned and allowed time for compliance with the law, may, on a twenty-four hour notice cause the building or the unsafe part of it to be vacated until the conditions of the law are fulfilled.

A common violation of the labor law is the failure to provide a fire drill. The attention of the fire commissioner should be called to this lack and more vigorous enforcement of this provision urged.

Whether or not automatic sprinklers are of value in the saving of life they are unquestionably useful in arresting and restricting the fire. Although their compulsory use is probably not expedient their extension should be encouraged. "Except in buildings over seven stories high, in which more than two hundred persons are employed above the seventh floor and in which wooden floors and trim are used, the authority to require them in the city of New York is vested in the discretionary power of the fire commissioner." It would seem to be no hardship if the limitations to the mandatory powers were removed and sprinklers required in all factory buildings over seven stories in height. The dangers naturally inherent in industries connected with garment trades make rulings essential to insure universal protection to the workers.

A Safety Device for Mines

Steel tool car in use at the Speculator Mine of the North Butte Mining Company, by means of which the miner can pipe air as he proceeds.

The modern metal mine is a large user of compressed air. To make compressed air available at the working places, it is necessary to construct pipe lines to the extreme limits of the mines. In a mine with extended levels, crosscuts and drifts, the piping problem is a difficult one. In order to facilitate this work some of the companies have designed a work car to carry a compactly arranged but

complete set of tools; which the *National Safety News* heartily recommends. The car carries a supply of nipples, unions, and other accessories, so that a pipe can be cut and threaded on the job. The car is a convenience as it confines the work of pipe construction to a small area and furnishes the proper tools for the work. It adds materially in preventing accidents to the pipe gang.

INSTITUTIONAL HEALTH

The Health Problems of Schools and Colleges, Hotels, Summer Camps, Children's Homes and Homes for Dependents

Are Prison Walls to Shut Out Science?*

Responsibilities of Prison Physicians in Combating Venereal Diseases

By VALERIA H. PARKER, M.D., DIRECTOR, DEPARTMENT OF PROTECTIVE MEASURES, AMERICAN SOCIAL HYGIENE ASSOCIATION, NEW YORK CITY.

IT NEEDS no more than a casual survey of medical statistics of penal institutions to determine the fact that, save in those established as separate reformatory institutions for women and girls, little advance has been made in either diagnosis or treatment of those diseases which more than any others are significant from a racial point of view and add more permanent dependents and defectives to be cared for by the taxpayers of the state than any other contributing cause. The exceptions to this are so few as to stand forth as conspicuous examples of progress amidst a general situation of neglect and lethargy.

Several years ago I was appointed member of a state commission to investigate the methods of diagnosis and treatment of venereal diseases in state and county institutions. At that time the state hospitals for the insane, the reformatory for men, and the industrial school for girls were the only institutions in which any attempt was made to examine every inmate for venereal disease, and to institute adequate treatment when positive findings resulted. The superintendent of the Reformatory for Boys stated that in a period of fifteen years there had not been a case of gonorrhea or syphilis in the institution, thus indicating that thorough physical examinations were not made. No reformatory for women existed at that time but when established later, provided proper facilities, while the state prison at a later date instituted routine examination and treatment.

In a vast number of our penal institutions the attention of the prison physician is given only to those cases of venereal disease which give unmistakable manifestations either through external lesions which elicit complaint from other prisoners or those which incapacitate a prisoner from performance of the work allotted to him.

That a high percentage of prisoners are infected with venereal disease there can be no doubt. The draft statistics compiled from vigorous young men outside of prison walls revealed fifty-seven infected out of every one thousand men. The physician of Sing Sing Prison, where most careful attention is paid to diagnosis and treatment of venereal diseases, finds an average of 21 per cent syphilitic and 60 per cent suffering from active or chronic gonorrhea.

Within the past decade, science has given the medical man accurate means for diagnosing both gonorrhea and syphilis through laboratory and microscopic findings, methods of thorough physical examination for chronic symptoms, as well as methods of treatment which if carefully applied over a sufficient period of time will eliminate the majority of venereal infections in the early stages and modify most chronic infections to a marked degree. The difficulties of controlling venereal disease outside of penal institutions may be grouped under the following heads:

(1) Difficulty in securing examinations of persons infected unless they consult physicians voluntarily or give evidence of such sexual promiscuity

as to warrant compulsory examination.

Compulsory examination of men under the latter circumstances is still of rare occurrence and there are valid objections to the compulsory examination of women before conviction of sex offenses.

(2) The patient frequently discontinues treatment after the most troublesome symptoms have abated.

(3) Symptoms are frequently aggravated by failure of patient to observe physician's orders, such as refraining from liquor, sexual intercourse, etc., while under treatment.

(4) Free clinics are not everywhere available and many cannot afford long continued treatment from private physicians.

(5) The quack, the charlatan, and the unscrupulous druggist too frequently secure the patient who believes in their promise of a quick and easy cure.

(6) Opportunities for reinfection after cure are ever present for the sexually promiscuous.

In all these points the prison physician has the advantage:

(1) Each potential patient can be compelled to submit to examination.

(2) Treatment can be continued as long as necessary while the prisoner is under sentence and in many states he may be detained until cured. In any case he may be reported to the Health Department upon discharge.

(3) The conduct, environment, and diet of the patient are under observation and control while in custody, together with prevention of intimate association with the opposite sex.

*Read before the American Prison Association, Detroit, Mich., October, 1922.

(4) Facilities for treatment are or should be at hand—provided by the state.

(5) Accurate medical knowledge, which should be possessed by any physician who occupies a position of public trust and responsibility for the health of others, is available.

(6) Little opportunity for reinfection after cure exists.

There are several reasons for the failure of prison physicians to meet the opportunity which is so evident:

Technical training in modern methods of diagnosis and treatment has not been available to all.

Those administering prisons and public funds have not realized the importance of increased facilities and appropriations for venereal disease work.

Antipathy to the work incident to the treatment of venereal disease still exists.

The responsibility for the treatment of venereally diseased prisoners seems to me to be greater than for any other group of citizens, if for no other reason than to protect the public at large. Their very presence in a penal institution indicates lack of self control which prison life may or may not remedy. The sex instinct, being the strongest instinct with the exception of hunger, is the one least likely to be controlled, therefore every uncured infection is a potential source of danger to others upon release. Gonorrhea leads to serious and damaging complications in its chronic form, while syphilis tends to progressive physical deterioration unless treated and cured, hospitals, institutions for the insane, and other public institutions will receive the tide which the prison might have stemmed. Among every group of prisoners will be found those whose very crimes were the result of congenital syphilis. Many uncured discharged syphilitics are potential fathers of such as these.

Recommendations for minimum standard of venereal disease care in penal institutions, therefore must be held to include:

(1) Adequate salary for prison physicians which shall encourage men and women of scientific skill to seize the opportunities offered by penal institutions as a field of medical service at less sacrifice than is now demanded.

(2) Physical examination of every prisoner for venereal disease.

(3) Laboratory and microscopic tests made either by the State Board of Health or a laboratory in the institution.

(4) Careful and continuous treat-

ment until repeated examinations give negative findings.

(5) System of social case work which shall establish communication with Health Officers in home community of prisoner in order that families of those found actively infected may be given benefit of treatment.

(6) No prisoner discharged while actively infected with venereal disease, and when discharged reported to health authorities.

I believe there are two reasons why a larger percentage of institutions for women and girls have adequate venereal disease treatment than those for men:

(1) The public in general has been quick to recognize the delinquent woman, usually sex promiscuous, as a potential carrier of venereal disease.

(2) Generally progressive methods of reformatories for women have necessarily included means for venereal disease treatment as a necessary agency in promoting her own welfare as well as that of the community.

Let us as physicians accept the new attitude toward venereal infection as a challenge to see to it that prison walls do not shut out the advances of science but only bar out those handicaps to medical care and treatment which are incident to the freedom of the individual in the outside world.

Near East Relief to End

ANNOUNCEMENT is made that The American Red Cross has fixed June 30 as the date for closing emergency relief work in Greece. For the past five months the Red Cross has been providing for 868,000 refugees as an emergent situation, but the solution of the problem is one not to be found by private means and it will be turned over to the joint consideration of all the nations involved.

It is stated, however, that the Near East Relief is prepared to continue to the extent of its ability the child wel-

fare work, including the support of 65,000 wholly dependent orphans now in its charge in the Caucasus, Greece, Syria, and elsewhere, and to continue supplementary work for a larger number.

The problem of finding permanent homes for the refugees is one, however, which is not within the scope of private relief agencies. It will require the cordial cooperation of the local authorities where the refugees may be situated, and of the powers whose territorial and other interests in the Mediterranean area may make it possible for them to assist.

The child welfare problem, considered apart from the solution of the adult refugee situation, will still command the attention of the American Red Cross. This picture shows some of the seventeen thousand youngsters cared for at the Near East Relief orphanage at Alexandroupoli.

State Program for Minnesota's Blind

BY SAMUEL A. CHALLMAN, STATE DIRECTOR OF SPECIAL CLASSES, PUBLIC SCHOOLS OF MINNESOTA, ST. PAUL, MINN.

THERE are in Minnesota 1,143 blind persons who are residents of the state, according to the latest available statistics. These persons have nearly all been served in one capacity or another by various public and private agencies in the state working for and with the blind. The service has, however, not always been of the most satisfactory nature either to the recipient or to the agency which has endeavored to render it. There has been on the part of both a desire to unify the work and make it more comprehensive in its scope.

In order to bring about such a condition the governor was asked to appoint a commission to study the situation and make a report of its findings with recommendations for a complete program according to which the work might be properly organized. The governor readily complied with this request and appointed a non-salaried commission.* This commission has devoted itself to the problem before it, and has given careful consideration to every phase of the subject. Its report has been placed in the hands of the governor, who has recently put it before the legislature.

The commission has given particular attention to the following matters: prevention, education, occupation and training, care and relief, and work of the supplemental agencies. Its recommendations are of two kinds: those dealing with legislative action and those dealing with problems of administration of public agencies by co-operation, and of co-operation with private agencies.

Legislation Proposed

In order to obtain the proper kind of organization for effective work, the

commission proposes that the present law in regard to a State Agency for the Blind be revised, and that the work assigned by law to this agency be placed under the State Board of Control. It recommends that the name, State Agency for the Blind, be changed to the Bureau of Public Welfare. It widens the duties and responsibilities with which the agency was formerly charged and authorizes the State Board of Control through this bureau to administer such appropriations as the legislature may make from time to time for discriminating care and relief of the indigent blind of the state.

In order that the special classes for the blind in the public schools may reach a greater number it proposes that the present law be so amended that a school district be required to establish a class, whenever there are eight or more pupils in the district who are eligible to such a class. The law now provides that any person of school age—5 to 21 years—being of sound mind who, by reason of defective sight, can not profitably or safely be educated in the public schools as other children shall be considered blind and is eligible to admission to a special class.

The commission also proposes that the State Board of Control, the State Board of Health, and the State Board

of Education coordinate their work, through the establishment of an advisory board made up of representatives from these bodies.

It also urges that an adequate appropriation be placed at the disposal of the State Board of Health for the purpose of combating the spread of trachoma. The need of this appropriation is very urgent, as evidenced by investigations made by representatives of the State Board of Health and the office of the Surgeon General of Public Health at Washington, D. C.

Taking up the question of prevention, the commission goes on record as urging the expenditure of public money for the prevention of blindness, on the ground that the state of Minnesota owes it to her children that their sight be safeguarded from birth, and that the state also owes it to its citizens to protect them from eye hazards and industrial diseases arising from modern industrial employment. The whole problem has been summarized as follows: (1) Most blindness can be prevented; (2) we have the opportunity of making it a disappearing problem; (3) the state has a responsibility for the control of blindness which it cannot escape; (4) the cost of prevention is small when compared with the cost of blindness; (5) it is a project in human conserva-

Blind reed furniture maker trained by the Minnesota Division of Re-education.

*Membership of the State Commission on the Blind is as follows: Mrs. C. W. LaDu, chairman, member State Board of Control, St. Paul; Hon. W. I. Nolan, member state legislature, Minneapolis; Hon. W. I. Norton, member state legislature, Minneapolis; Hon. Hilding Swanson, state senator, Brainerd; J. B. Sanborn, District Judge, St. Paul; E. G. Steger, district Mutual Aid Blind Association, St. Paul; Mrs. I. L. Rybins, president, Mutual Aid Blind Association, St. Paul; Oscar Sullivan, state director Division of Re-Education, St. Paul; George P. Meyer, supervisor special classes for the blind, Minneapolis; Dr. C. A. Prosser, member State Council of Agencies for the Blind, Dunwoody Institute, Minneapolis; Miss Edith Marsh, executive secretary, Minneapolis Society for the Blind; Frank Jordan, member Minnesota Organization for the Blind; Mrs. A. W. Strong, president Minneapolis Society for the Blind; Prof. M. C. Elmer, professor of Sociology, University of Minnesota; Bertha Hanford, state and county agent for the blind, Duluth; Jean Poirier, president St. Louis County Association for the Blind, Duluth, and Hon. Charles E. Adams, state senator, Duluth.

David Rau, a blind man employed by the Minneapolis Society for the Blind as weaver of pattern rugs. Now teacher of weaving in the Minnesota School for the Blind at Faribault.

tion; and (6) justice requires that Minnesota safeguard the future of every child.

The importance of a definite program of prevention is conclusive when it is considered, first, that relief measures for the blind without such a program do not lessen the amount of blindness; second, the conditions of modern life including universal education and close work with artificial lights have brought about increased eye strain; third, eye hazards in industrial occupations have increased the number of blind with the development of these occupations; fourth, science and human experience have discovered many of the causes of blindness and the remedies for some of them; fifth, due largely to present measures of prevention, meager as they are, blindness at present is not on the increase; sixth, socially as well as financially, the prevention of blindness is an economic asset; seventh, leading authorities estimate that approximately two-thirds of the cases of blindness now existing are due to preventable causes. All this indicates that we need to extend opportunities for medical and surgical aid to all persons in danger of impaired eyesight, and in order to reach them, it is often necessary to search them out and provide treatment for them at public expense. The public in general stands in need of education in regard to the care of the eyes, the danger from contagious eye diseases, the effect of venereal diseases upon

the eyes, the safeguarding of individuals in employments which tend to bring about loss of sight or diseases of the eye, and the causes of blindness as well as the ways in which it may be prevented or arrested. Eye clinics conducted by the State Board of Health, private hospitals, and municipalities are strongly recommended as are also courses of instruction in the public schools in the

hygiene of the eye and periodic examinations of the eyes of all school children.

The report of the Commission deals at length with the importance of the education of the blind. It emphasizes the fact that instruction must be essentially individual in its nature, a very broad field must be covered under difficulties, the simplest imitative movements of the sighted must be carefully mastered, and, finally, the curriculum must be rich in the development of latent natural talents. Such a policy is of necessity costly, but it is an obligation which the state must accept. The education of a blind child should begin at the earliest possible time so that those elements in his education, which come naturally into the life of the sighted child through imitation, may be instilled before wrong practices are acquired. Much of this training should precede the child's admission to school and should be conducted in the home so that the home ties may be preserved as long as possible. Such pre-school training of the right kind will conserve time later on, when the child enters school and spare him much discomfiture which he is otherwise likely to experience in adjusting himself to the conditions of life which exist outside of the home.

The State School for the Blind is located at Faribault. A few children just over six years of age are admitted to this school, under exceptional conditions, but the usual age at which children enter is eight years.

Exhibit of work done by the blind.

Special classes for the blind are provided in five of the larger public school systems of the state. The age of admission into these classes is five years, but only a very few children enter before seven years of age. School systems in Minnesota are encouraged under the present law to establish classes for the blind by a grant of state aid to the amount of \$300 for each pupil who is enrolled throughout a school year of at least nine months, on the condition, however, that there must be enrolled not less than five children. The commission proposes, as already stated, that school districts be required to establish a class whenever there are not less than eight children in the district for whom application is made.

The report contains a detailed discussion of the principles and aims that should govern the state school for the blind on the one hand and the special classes in the public schools on the other. It discusses the needs of Braille readers and children with impaired sight who need large type books. It recommends better service for sight-saving classes and increases state supervision of these classes. It suggests the establishment of sight-saving classes in the State School for the Blind. It advocates a readjustment of the music department in order that it may better serve the pupils according to their varying activities, abilities, aptitudes, aims, and needs. It endorses the present provisions for awarding scholarships for higher education to the amount of \$300 to each of a maximum quota of five promising blind persons and urges that greater publicity be given to this feature.

In commenting on the occupations and training of the blind the commission points to the fact that the tendency to huddle them into a few vocations is a segregating tendency and

Blind drill press operator

results in abnormal situations. The blind have ordinarily sought employment along the lines of handicrafts (basketry, weaving, chair caning, broom making, salesmanship—usually of the canvassing variety—piano tuning and occasionally massage and dictaphone work). Some have gone into the professions, but their number is very limited. The traditional handicrafts are gradually becoming obsolete. Factory work is becoming more diversified. The blind must find new occupations to make up for the disappearing ones.

The division of re-education in the state department of education has given much attention to this problem. In the course of its investigations, it hired a blind man to go into factories, with which arrangements had been made, for the purpose of demonstrating whether or not such a man could satisfactorily perform work of various kinds. The result of this man's work and of a survey carried on by the division showed that there were 90 processes in 17 kinds of industries that could be performed by blind persons. The industries listed by the division are: small machine parts shops, paper box factories, knitting works, automobile body building and repair shops, novelty advertising companies, electric light globe factories, wooden box factories, paper and cloth bag manufacturing plants, clock and chimes manufacturing plants, candy manufacturing plants, coffee companies, cigar manufacturers, wholesale hard-

ware companies, bed manufacturers, flour mills, linen supply companies, and food manufacturing plants.

The commission recommends that a consistent and united effort be made by all public as well as private agencies dealing with the blind to extend the number of occupations open to them. It advises that, owing to the small demand for handicraft products, learners be directed away from this particular type of employment as fast as it is possible to find other lines for them. It suggests further study and research into factory employment. It advocates the adoption of plans for vocational guidance for the state school, the special classes in the public schools, and the Division of Re-education. It commends the work done by the private agencies in finding employment and providing work for blind persons, and calls attention to the fact that nearly \$14,000 was taken in by these agencies in 1921 from sales of products.

For the care and relief of the indigent blind, the commission proposes that the per capita allowance shall not exceed a maximum of thirty dollars a month for one blind person, or, in case two blind persons marry after the passage of this act, the same amount. From such relief are excluded all blind persons who solicit alms, or are inmates of public institutions, or of charitable institutions and are supported without charge to the blind person himself, or to any blind person who has for five years preceded-

Sightless typist of Minneapolis, Minn.

ing loss of sight been dependent upon public relief. Persons who apply for relief must show that they are citizens of the United States, that they have become blind while legal residents of Minnesota or that they have been legal residents of the state for not less than five years prior to making application for relief, that they are unable to provide themselves with the necessities of life, that they are without relatives who are able to support and care for them, and that they will, unless given relief, become charges upon the public. Any persons receiving such relief thereby automatically become ineligible to any help from any other public funds.

The commission recognizes that volunteer agencies are an invaluable factor in promoting the welfare of the blind. Such agencies are the challenge to the citizenship to contribute such service as will make the law an effective living force, provided they are earnestly seeking to promote the success of the state program.

Minnesota is fortunate in having several such agencies, each of which is represented on the commission by one or more of its members. These private agencies have in the past been, and it is the intention of the commission that they shall continue to be a valuable link between the various state agencies and the people who are seeking help from the state. In addition to this they are in a position where they can render assistance beyond the limitations imposed by law on state agencies. Their work does and can cover a great variety of activities, ranging from intimate home service and socializing influences to bringing to them opportunities of work, of training, of developing markets for their products, of providing places for manufacturing purposes, and of assisting them in their business relations. The commission goes on record, after its exhaustive study of the subject, as affirming that there is yet much to be learned about the problem of the blind, and that there are new methods to be worked out. It finds that the pioneer work as well as the advanced work beyond the limits fixed by law can best be done by volunteer agencies.

The complete program for these agencies, put into a nutshell, would include such services as: (1) bringing to the attention of public agencies such individuals and conditions as need their services and attention; (2) doing educational work in homes containing blind persons chiefly children of pre-school age. This includes, of course, interesting sighted members of

such families as well, so that they may be aided in understanding the problem of their own blind and adjusting themselves to it; (3) searching out industrial opportunities for the blind in normal industry, and educating employers to the possibilities of blind people as desirable and profitable employees; (4) organizing volunteer individual service to supply the individual interests and the personal touch which the state agencies can provide for only in a small measure.

In conclusion it should be noted that the above is only the briefest kind of summary of this voluminous and very interesting report. For want of space,

many matters, discussed at length in the report, have been given only the merest mention or have been omitted entirely. It is to be hoped that the high lights have been brought into prominence and that the thorough and comprehensive work of the commission may result in a great many benefits to the blind as well as to those who in years to come will be saved from blindness by preventative measures. In the words of the commission: "Every dollar spent on such a program will be certain to yield continuous deferred dividends in a reduced social burden and in an increased number of self-reliant, intelligent useful citizens."

Vitamins in Meat

MEAT has long been one of the most important articles of food in the dietary of the American people. In pounds the 1922 per capita consumption was as follows: Beef, 57.7; veal, 8.3; mutton and lamb, 6.1; and pork, excluding lard, 72.8; a total of 144.9 pounds per year, or 0.4 pound per day. Meat forms, together with poultry, 16 per cent of the aggregate American dietary as compared with 18 per cent for dairy products, 25 per cent for fruits and vegetables, and 31 per cent for cereals and their products. Meat also furnishes 30 per cent of the protein and 59 per cent of the fat in the dietary.

Even more striking is the relatively large expenditure for meat as compared with other classes of foods. H. C. Sherman has stated that as a result of a dietary study of 2,567 workmen's families, the United States Bureau of Labor Statistics found that the average expenditure for meat, poultry, and fish amounted to 33.8 per cent of the total cost of food.

Much importance recently has attached to studies planned to determine the vitamin content of average diets and the statement has frequently been made that meat in general is poor in vitamins. A careful study of the literature indicates that only a limited number of investigations have been carried on to determine the vitamin content of meat foods, and that has been done with beef and horse meat.

Of great interest, therefore, is the government report just issued as Bulletin No. 1138 of the U. S. Department of Agriculture of studies made by Ralph Hoagland on vitamin B in the edible tissues of the ox, sheep, and hog. The study is in two parts,

one devoted to determinations of vitamin B in the voluntary muscle, and the other on vitamin B in the edible viscera.

The experiments detailed in Part 1 of the report were to ascertain the antineuritic properties of the voluntary muscle of the ox, sheep, and hog when fed to pigeons in connection with polished rice. Forced feeding was used in the experiments, the meat employed was of the best quality. The rice was the ordinary polished rice of commerce. When symptoms of polyneuritis developed in the birds, they were promptly fed dried yeast, to which treatment most, if not all, the affected birds responded readily. It is interesting to note that birds with the acute type of the disease yielded to treatment much more readily than did those with chronic forms.

The results of the work indicate that ox muscle has a much lower antineuritic value than hog muscle. If meat were to be the sole source of vitamin B in the diet, or even the most important source, pork would be preferred to beef. Given an ample supply of the vitamin B from other sources, the antineuritic properties of beef, pork, and mutton become a matter of minor importance.

The method of investigation with edible viscera was practically the same as with the voluntary muscles. Several of the internal organs were found to be particularly rich in vitamin B. The heart appears to be the richest in this vitamin, but the liver and kidneys have only slightly lower values. The other organs contain smaller quantities of the vitamin, but the study proves that this class of products is an important and economical source of vitamin B.

Sunlight Treatment of Surgical Tuberculosis*

CERTAIN forms of radiant energy, notably the ultraviolet and x-rays, have received considerable reputation in therapeutics. "Sunlight in comparison with these radiations," says A. Rollier, medical director of the heliotherapeutic institution at Leysin, Switzerland, "has received but little attention." But little explanation can be offered for this except that man has a tendency to attribute particular virtue to rarity. The prescriptions of medieval physicians contained such ingredients as tongues of adders and skins of toads. We now know that air and water (with a little soap) are much more useful guardians of health than a whole pharmacopeia. Sunlight is another cheap and universal tonic deserving of much wider application than it at present receives.

The virtues of sunlight have not, however, passed unnoticed through the ages. Writers on medical subjects in classical antiquity made frequent references to the therapeutic action of the sun. Even as early as the days of Herodotus the dangers were understood of exposing cachectic patients to the sun's rays during the heat of summer. The dark ages naturally saw heliotherapy sink into disuse, but by the middle of the eighteenth century sunlight again interested the medical profession. Faure, in 1774; and Bonnet, in 1845, renewed its use. More recently it was taken up by Poncet in Lyons, France, in his effort to avert the great number of recurrences after brilliant surgical work in tuberculosis. Berhard in 1902 used insolation in the treatment of wounds.

It was in 1903 that Rollier opened at Leysin the first clinic for the systematic treatment of surgical tuberculosis by heliotherapy. From the first he considered the action of sunlight upon the whole surface of the body as of more importance than the direct effect of the sun on the tuberculous lesion. During the first few years he used plaster casts for fixation of the affected parts and performed a certain number of excisions. But the efficiency of the sunlight

treatment had been underestimated and operative intervention became more and more rare. Even fixation by means of plaster casts has been abandoned in favor of apparatus which provides sufficient immobility without interfering with access of air and sun to the affected part.

The aim of heliotherapy is to place the debilitated body of the patient in an environment which will in the highest degree favor the recovery of general health and in this way to increase the resistance of the body to tuberculosis. The sun bath, however, is by no means the only factor of importance in this environment. The system of treatment known as heliotherapy attaches the greatest importance to fresh air, which is not only breathed day and night, but comes into intimate contact with the whole surface of the body during a large part of the day. Diet and hygienic habits also have their importance.

The manner in which beneficial effect of sunlight upon the body is effected is but little understood. Sunshine *per se* promotes that contented and happy frame of mind which in itself is conducive to health. It is analgesic. Painful symptoms soon disappear even in cases in which rest alone has been insufficient to produce the effect. Though the amount of energy absorbed from the sun and the manner in which it is utilized by the body are not explained, opinion seems

to lean to the belief that the red rays, rather than the violet rays, are to be credited with the tonic effect which restores the functions of the anemic skin, and produces the splendid muscular development which takes place even in patients who are confined entirely to bed. Whatever complexity of heat stimulation, of electrical or chemical phenomena are involved, function is restored in cases where it could scarcely have been hoped for.

There are great individual differences in the adaptability of patients to this form of treatment. The procedure is initiated with great care and progressive insolation carried on in strict accord with the tolerance of the patient. Exposure always begins with the feet, the legs, thighs, abdomen, and thorax, following in this order named, with an interval of a varying number of days between each. Only a few minutes of exposure are permitted at first, but the amount is gradually increased until the patient is able to expose the whole body to the sun for several hours daily without any inconvenience in summer or winter.

Heliotherapy may be carried out in any place where the sun shines, but different places show great variation in the quality of the sunlight. High altitudes are preferable, where the air is transparent, free from solid particles, and easily traversed by the sun's rays without absorption, so that

Clinique "Les Frênes" Leysin. One of the first institutions of Dr. Rollier, specially built for the purpose of heliotherapy.

*The materials for this comment are from A. Rollier, M.D., medical director of the heliotherapeutic institutions at Leysin, Switzerland. Reference is made to the following articles:

Sun. Its Place in the Treatment and Prophylaxis of Tuberculosis. Brit. J. of Tuberculosis, xvi, No. 1, pp. 1-13, 1921.

Heliotherapy in the High Alps. Lancet, cc. No. 12, pp. 582-584, 1921.

Construction of an Institution for the Heliotherapeutic Treatment of Surgical Tuberculosis. Tubercle, ii, 241-250, 1921.

Clinique "Les Chamois" Leysin, 4,500 feet above the sea level, the highest of Dr. Rollier's institutions.

they warm and invigorate the body of the patient while leaving the air cool and fresh. For this reason a much greater intensity of direct sunlight can be borne at high altitudes, and heliotherapy may be practised in mountainous regions every month of the year. In giving directions for the location and construction of an institution for heliotherapeutic treatment, Rollier directs that a place more or less protected from winds be chosen where there is as much sunlight as possible and where the air is sufficiently bracing. The ideal height is between three and five thousand feet.

The construction of palatial buildings for such an institution is by no means necessary. Excellent results may be achieved with improvised arrangements. It is merely necessary that climatic situation and management conditions be fulfilled. There are three types of buildings at Leysin. The first heliotherapeutic institution was a converted mountain chalet, an annex being provided with balconies so placed as to receive the sun's rays the whole day. Solariums were built where balconies were inadequate, each solarium being equipped so that patients can be taken to it without leaving their beds. On the second type of building at Leysin, a converted tourist hotel, a solarium was constructed on each floor on the southwest end of the building.

The third type of building at Leysin is of interest as it was arranged entirely with a view to practise heliotherapy on Rollier lines. The building consists of a central block and

two large wings. The control block faces due south. It contains on the ground floor consulting rooms, radiographic and radiotherapeutic departments, rooms for orthopedics and phototherapy. The bacteriological laboratory and offices are also housed here. On the first floor are the dining room, billiard and smoking rooms. On the fourth floor there are rooms for surgical dressings and an operating theater. This latter room is used only for non-surgical infections. Operative interference in tuberculosis is minimal. The left wing of this

building faces slightly east of south. The balconies of the different floors are terraced so that the light falls perpendicularly. They are but little sheltered from the wind and sunlight and are therefore more suited to slight cases and to those already used to the cure. In summer the sun-cure begins here in the short hours of morning.

The right wing faces considerably west of south. Each room has a private balcony, separated from adjacent ones by movable screens. The balconies are covered. The duration of sunlight is of course shorter, but to make up for this they are more sheltered, this being an advantage in winter. On the first floor all balconies are reserved for children. The partitions are removed so children can play together and enjoy the entertainments provided. A teacher attached to the sanatorium gives lessons on the balconies. These lessons take place in the sunshine and fresh air. Except in cases of quite young children, boys and girls are kept separate.

To arrange for the relative shortage of sun balconies, an extensive solarium covers the whole roof. Patients are brought up on a lift in their beds. All floors are exactly on a level so that beds can be wheeled easily without jolting. The patients are wheeled everywhere on their beds, to the smoking room, moving picture theater, etc. The beds are high, to prevent interference of balcony rails with sun cure or view. They are fitted with large solid wheels (14 inches in diameter and one-half inch thick). Special

Heliotherapy in Dr. Rollier's institutions. Clinique "Les Frères," Leysin: a children's balcony for the sun-cure.

mattresses are provided, very hard, in order to prevent the patients taking a bad position as may happen with a soft, springy mattress. The spring mattress is constructed of strips of metal with wide spaces which assure permanent aeration of the mattress. The patients soon come to prefer the hard mattress to a soft bed. The beds are fitted with movable shades, so that the head of the patient can be shaded whatever position he may be in. Linen strapping is depended upon for the required immobilization so arranged that it can be opened and closed so as not to interfere with sun cure.

An important accessory to heliotherapy is the work cure. It is considered at Leysin that the moral condition of the patient suffers in inactivity and that regular, but not tiring work is desirable. Strictly supervised activity forms a mental stimulus that is highly beneficial. An open air school is maintained as an ideal half-way house for the convalescent and for preventive work in the predisposed. The school work is subsidiary, its object being merely to keep the mind in discipline. The use of very light folding desks and stools makes it possible for lessons to be held in the fields and the woods, the site being chosen according to the heat of the day. Much attention is given to Swedish drill, as proper chest expansion and nose breathing are regarded by Dr. Rollier as a very useful prophylaxis against a multitude of diseases. The school has abundantly proved that there is no surer way of building up the body's resistance than

"Preventorium" for children predisposed to tuberculosis, otherwise known as the "School in the Sun, Les Noisetiers," at Cergnat near le Sepey.

life in the open air and sun. "Until we apply this knowledge to the conditions of our everyday life," states Dr. Rollier, "tuberculosis will continue to exact its heavy toll of victims each year." The results obtained in the open air schools give reason to believe that in almost every case the disease may be completely eradicated before any manifestations take place, thus avoiding much suffering and expense.

The bill requiring all applicants for licenses to practise medicine to know something of physiology, anatomy, and pathology, has been defeated in the Minnesota State Legislature.

Prevention of Hospital Fires

It is startling to learn that, during 1919 and 1920, 870 fires occurred in institutions classified as hospitals, asylums and sanatoriums,—an average of more than one fire a day in that type of institution. If any structures should be properly protected, those in which human beings lie incapable of self-protection should be given first consideration, states the *Journal of the American Medical Association*. Among the causes of fire in these institutions were, first, sparks on the roof; second, defective chimneys and flues; third, lightning; fourth, heating installation, and fifth electricity. These etiologic considerations point the way to prevention, but there are further special considerations which apply to hospitals. The height of hospital buildings is a matter for concern; ambulatory patients should be placed on the higher floors, the lower floors being reserved for those completely bedridden. In every hospital, there should be located fire alarm boxes for prompt notification in case of fire. Volatile liquids which are easily inflammable should be handled with caution. Chemical extinguishers should be easily available, and a fire drill for the employees should be regular experience. "When it is realized," says the National Board of Fire Underwriters, "that most fires are preventable, and that there are none too many hospitals, it seems a pity that owing to the neglect of fire prevention measures large sums must go annually toward replacing what might have been conserved for further usefulness."

Heliotherapy in Dr. Rollier's institutions. The solarium-roof at Clinique "Les Frères."

University of Cincinnati Dormitories*

EVERY possible means of sanitation taking in all modern features are being installed in the new dormitories of the University of Cincinnati. The dormitories, both within and without, have been planned so as to create a feeling of contentment among the students who will live there, and through this, aid materially in the quest for knowledge during the four year course of school. The dormitories will enjoy to the utmost sunshine and fresh air as they will be isolated from the college buildings, and yet will be well within the rolling campus of Burnet Woods in which the school is located. Burnet Woods is one of the most picturesque parks in Cincinnati and affords a wonderful setting for one of the few municipally owned universities in the United States. Burnet Woods abounds in fresh air as it rests high on one of Cincinnati's seven hills and is beyond the pale of any manufacturing district, consequently assured of freedom from smoke and grime of the latter.

The dormitories are planned and being built as a continuous group of separate units, forming two large hollow squares, with entrances to the courts or quadrangles by means of large vaulted passage-ways.

The buildings will be of four stories, designed after English collegiate architecture, the walls comprising mingled shades of red brick and stone colored terra cotta trimmings and with a mottled green slate roof, forming a pleasing yet dignified style of construction. The units will each contain approximately forty

rooms in which sixty students will be housed as half of the rooms will be single and the other half double. Three of these units, together with a memorial tower, are now being erected on a low hill south of the gymnasium building in the southeastern part of Burnet Woods, and with the completion of the twenty-two individual houses, there will be an ultimate capacity of 1,137 male students.

A memorial tower will dominate the entire group as it is to be 84'-0" high from base to parapet, with the first floor containing a memorial room dedicated to the students who served during the World War.

Although the buildings will be heated with a vacuum system of steam heat, at least 25 per cent of the rooms will be provided with open fire places. Each and every room will also have large windows of casement sash and weather stripped, in order to secure full advantage of openings when so desired. Rooms and halls throughout will be covered with mastic flooring, laid over concrete, thus assuring a sanitary and elastic flooring. Each room in its make-up will provide a capacious closet, plate rack, a metal bed, desk table and two chairs together with electric ceiling and lamp outlets. While there will not be individual telephones each floor will find a talking instrument on it with buzzers in the rooms as a means of notification. A large toilet room will be provided on every floor with showers and other fixtures of modern type surrounded by walls, partitions and wainscoting of pure colonial gray marble. An office will be on the first floor off the main en-

trance near the memorial tower for the custodian and in which all outgoing and in-coming mail will be handled. With the completion of these buildings it is hoped not only to provide living quarters for out-of-town students at a minimum cost, but also create college spirit which seems to be lacking at U. C. With students eating, sleeping, talking and studying "U. C.," the alumni hopes there will be engendered at Varsity the same clannish spirit and atmosphere that prevails about the larger colleges in the East. There is being completed a stadium about Carson Field, one of the most natural amphitheaters in the country, and this together with the dormitory is looked upon as a sure source of real dyed-in-the-wool college spirit. Commodious, comfortable, architecturally interesting, grouped to assure a maximum of efficiency in matters of administration, and to afford sunlight to all rooms, the dormitories meet every present and future need of the student community.

The dormitories were designed by Harry Hake, architect, and Charles H. Kuck, associate.

The council of Esmeraldas Canton, Ecuador, has signed a contract with an American engineer for the construction of a sewer system, drinking-water system, fire hydrants, and electric lighting, to be installed within two years, reports the *Bulletin* of the Pan American Union. The Canton of Vinces is also to have electric light and sewer systems for which taxes will be levied on each vessel or small boat entering the port of Canton beginning January 1, 1923.

The new dormitories of the University of Cincinnati rest high on one of the city's seven hills. They are being built as separate units, forming two large hollow squares.

Entrances to the courts or quadrangles are by means of large vaulted passage ways. Each unit will contain approximately forty rooms. All rooms are provided with large windows.

Organizing a Student Health Service*

By JOSEPH E. RAYCROFT, M. D., PRINCETON UNIVERSITY, PRINCETON, N. J.

AN APPRECIATION of the value of building up a coordinated and efficient health service is growing rapidly among educational authorities. The number of institutions that have attempted to make additional provision for safeguarding the health and working efficiency of their students is increasing yearly. The character of the organization set up for this purpose varies in some respects in almost every institution, due to differing conditions.

Whenever the organization of a student health service is discussed, there instantly arise two troublesome questions: What will be its relations to the work and the men in physical training and athletics? where is the money coming from? Too frequently the answer results in adding a new cog, which is independent of others, in the student health machine. In some places the hospital service is quite distinct from every other phase of institutional life that may affect the health conditions. In others the dispensary service is separate from, and under other management than, the hospital service; and neither has any affiliation with the routine physical examinations made by the physical education department. In still other instances there is no relation to competitive athletics either as regards supervision of contestants, treatment of injuries, or decision as to the length of time that should elapse between discharge from the hospital and return to training and competition.

This lack of coordination in matters that affect physical welfare, is the rule rather than the exception, and stands out in marked contrast to the administration of the classroom subjects.

The existence of these conditions in various combinations serves to make the development of a satisfactory health service uncertain and difficult. For this reason a constructive discussion of two or three of the outstanding points of difficulty may be of interest.

The first point has to do with the financial support for a dispensary and hospital service. This should be neither so expensive to the student as to limit his use of it, nor should it be on a charity basis. We will agree also that the plan of financing the work

Student health service gets its value from the fact that it conserves selected groups within the selected group of the best youngsters in the country. Social investment in health should not lag behind social investment in general education.

The care of student injuries on the athletic field is herein depicted as a specialty. Shall any less than the best judgment of our best medical men determine who shall train, who shall be denied athletic activities, and what measures and apparatus are requisite to restore the student jeopardized by field and gymnasium activities?

should be such as to permit the authorities to make a dependable budget from year to year. It is a serious question whether the institution is justified in using any of its current funds for hospital service, even if most of them were not running an annual deficit in the regular budget. I do not wish to be understood as opposing the provision by the institution of an adequate plant for the health service—I refer simply to the budget for maintenance and administration; nor do I think that the plan of charging a fee, even a small one, for each treatment by the health service is desirable or practicable. On the whole, the most desirable method of financing such a service seems to me to be through an annual health fee which is collected with tuition, laboratory fees, etc. This may be regarded as a form of health insurance, which will entitle the student to such medical or minor surgical treatment as may be necessary, and which places the poor student on the same basis as the one of wealth so far as this service is concerned. The hospital should be administered on a democratic basis, students being assigned to ward or private room according to the nature of the case. The fee will cover all expenses incident to sickness except those of an exceptional nature, *e. g.*, operating room charges for operations requiring full anaesthesia, a nominal fee for x-ray pictures or for special nurses. Since all students are on the same basis, no one will hesitate to go to the hospital or dispensary for treat-

ment. Over 87 per cent of the students made some use of the infirmary at Princeton last year. Other advantages of this plan are that a very small percentage of the students will go to the town physicians, which means more complete information about student sickness and more perfect control of contagious cases; the number of students for the next year can be pretty closely estimated, and the budget can be worked out accordingly. The plan outlined above has been used at Princeton for years, and the health fees, plus the income from a small endowment, have been sufficient to meet the expenses of the hospital, including salaries of medical, nursing, and housekeeping staffs.

Many of us have had the experience of being sick away from home, or of visiting a youngster who was sick at school or college. It's a lonesome situation. An allied service that is most valuable under such circumstances can be rendered by a visiting committee of faculty ladies or others in the community who can be of the greatest help in little friendly ways to both the patient and his visiting parents. At the same time they can greatly relieve the frequently overworked staff of certain personal services to visiting parents and friends of the sick students.

The second point has to do with the type of physical examination, and the way in which it can be conducted so that it will serve both medical and physical education needs.

The physical examination of new students should lay special stress upon several important points:

(1) A record of previous sickness; injuries; eyestrain; tendencies to cold and constipation; rate of growth; habits of living; sleep; exercise; experience in various physical activities, sports, games, etc.,—all this by way of history.

(2) Observations of a sort that deal with functions should cover heart, lungs, kidneys, eyes, ears, etc., as opposed to measurements, which might be limited to height, weight, and chest mobility. Observations should be limited to those that are useful; all others should be omitted and the time saved for such conference and personal advice as may be indicated by the individual examination.

(3) Cards that contain records of

*President's address at the meeting of the American Student Health Association, December 26, 1922, New York City.

special conditions should be designated by clips of various colors, so that cases of a given kind—heart, kidney, etc.—can be easily distinguished from normal records, and so be always available for “follow-up” examinations and conferences by either the medical man or the physical director. This scheme for distinguishing types of conditions is most useful, and makes the examination a much more valuable factor in the follow-up and preventive work of the general health service.

Still another point of importance is to work out a method of making the observations so that the examination may render the greatest service to both the medical and the physical education staffs. This can be accomplished by dividing the items of the examination among various examiners, according to their special interests, *e. g.*, a series of stations in adjoining rooms; in the first, height, weight, chest mobility, posture, feet, spine, taken by a member of the physical education staff; in the next—a dark room—eye, ear, nose, throat, hernia, by a medical member or a specially trained layman; in the third, heart, blood-pressure, lungs, kidneys, general condition, by a medical member; then to the gymnasium floor and the swimming pool for the physical efficiency tests, and swimming and life-saving test. Each examiner will make his own notes, give such advice as may be necessary, and will attach a tab for future reference. The last medical man checks the whole examination, sums up the advice, lays out a special program, or makes appointment for later report and conference if necessary.

This plan of examining and indicating special conditions simplifies and stimulates the follow-up scheme, which increases the value of the whole procedure, and enables anyone, with a minimum expenditure of time, to keep in touch with the progress of special cases.

This examination record follows the student to the infirmary, where it serves to put the attending physician in touch with the normal condition of his patient, and frequently gives him valuable information. When the student is discharged, a record of the sickness, its kind and duration, is made on the card, and serves as a guide for advice as to resumption of physical activity and methods for avoiding a recurrence of certain sicknesses, such as gastro-intestinal, respiratory, etc. This is a most effective method of teaching hygiene, as well as of keeping students fit to work.

The last point which I wish to stress is the relation of the health service to the supervision of competitive athletics, and the care of the injuries received in athletic activities. Here is a point where the newly installed health service is likely to run into trouble. Even where the institution is fortunate enough to secure for its health service men whose ability in medicine and surgery is outstanding and acknowledged, the trainers and rubbers are likely to regard with suspicion any suggestion that looks toward lessening their authority and responsibility for the condition of the teams and for the care of the injured. As a result, in many instances even where there is a team physician, the care of injuries is empirical and inadequate. I do not need to emphasize to this group the very great value of prompt and proper attention to an injury whether bruise or sprain. A relatively brief delay in instituting proper treatment frequently means a considerable loss of time and the difference between complete recovery and partial disability. The treatment of minor pus infections is frequently such that only the splendid defensive powers of the man in training prevents serious results. When these defensive powers are weakened by local injury or by general staleness the bad treatment bears its full fruits of extension of infection and prolonged incapacity.

The fact that there are trainers who are using effective methods in the treatment of these conditions is not overlooked, but they are greatly in the minority. But whether the fault lies at the door of the surgically ignorant team physician or the trainer or rubber, the fact is that much of the attention given to injuries received in athletic activities is very bad. This is not an easy situation to correct for the reasons mentioned a moment ago, but the great increase in athletic sports and games, involving as they do, many more students than was true even a few years ago, emphasizes the necessity of reorganizing this whole business of the care of athletic injuries and giving the students the right sort of treatment at the right time. It must be recognized at once that the ordinary doctor without special training is not generally competent to handle these cases successfully. The situation calls for familiarity with special measures and apparatus. The fluoroscope and the x-ray pictures should be freely used; electric baths, diathermy, and hydrotherapy can be provided with the fees that are paid surgeons whose services

are otherwise needed to correct conditions due to bad or delayed treatment in the beginning.

The point is this: Here is a situation that in many cases is handled in a way that is as obsolete as the midwife practice of obstetrics. Involving as it does the welfare of the best youngsters in our institutions, it should be handled under the supervision of the health service by the best men that can be obtained. The same principles obtain in the decision as to whether or not a student may take part in athletics, or as to when he may return after an illness. Correction of these conditions will depend largely on two factors: the recognition by the institution of its responsibility to bring about improvement, and the personality of the doctor and his tact in dealing with the athletes and trainers all working for improved methods, the proper coordination of treatment and the protection of the student. Society's investment in the relatively small number of people who get as far as high school and college in educational training, is too great to be jeopardized by ignorance or neglect on our part. It's not easy to set up an effective system of teaching and protecting student health, but success richly repays the effort.

Carbon Monoxid Recorder

Work of the Bureau of Mines on the ventilation of vehicular tunnels has developed the need of an instrument to record continuously carbon monoxid over a range of concentrations up to about 10 parts in 10,000. For this purpose an instrument has been designed at the Pittsburgh, Pa., experiment station of the bureau, using multiple, differential thermocouples with a catalyzer between the junctions to cause carbon monoxid to combine with oxygen of the air. The heat of reaction produces across the thermocouples a potential difference which, as a measure of carbon monoxid concentration, it is proposed to record with a recording potentiometer. When the instrument is set up it will be calibrated with known mixtures of carbon monoxid in air. If it proves practicable, the instrument will also be useful around mines, blast-furnaces, metallurgical and chemical plants, gas making plants or wherever carbon monoxid creates hazards.

Careful research has shown that in a factory where 300 are employed (75 per cent being women) that 80 per cent of the total will use the lunch room.

An Effective School Design at Wayzata, Minnesota

By EDWIN H. BROWN, HEWITT & BROWN, ARCHITECTS, AND CHAS. L. PILLSBURY COMPANY, CONSULTING ENGINEERS, MINNEAPOLIS, MINN.

THE question of a new school building at Wayzata arose very suddenly owing to the fact that the previous building, like its two predecessors, burned to the ground in the middle of a school year. The school board, the chairman of which was Mr. J. E. Spencer, showed their wisdom as business men by engaging their architect at once before any set plans as to the new school should be carried out. At the same time a scheme was put on foot for consolidating a number of school districts in that vicinity and having the people vote the necessary bond issue for erecting a school appropriate to their needs. All of this was carried through successfully, and the architects were put to work to solve the school problem for Consolidated District No. 144.

As in all country districts, the load of taxes caused by expensive school buildings may be heavy and here, again, the school board showed its wisdom and farsightedness. As the architects were in thorough accord with the ideas laid down by the school board matters proved not too difficult. Roughly, the fundamental idea of both the school board and the architect was that a school building was needed which would give adequate housing for the number of pupils that were expected, with a reasonable allowance for growth, the children to be housed in amply lighted, well ventilated rooms, and the too great number of so-called modern specialties in education to be kept in the background, but the primary fundamentals of education, the "three R's," to be emphasized.

Then came the interesting problem

of getting a building large enough for the needs within the appropriated sum of money. Preliminary plans were put out for a typical standard type of three story school building, which it was found impossible to build for the money required. Then two stories were tried, then a very simple arrangement of a one story plan was worked out and, figuring that this could be accomplished for the sum of money, the architects were instructed to proceed, plans were finished, specifications and all of the necessary details for the complete and finished job were put into the hands of contractors for bidding in the late fall of 1920. To the gratification of all concerned the building came well within the limit set, the contracts were let, and the school finished ready for the pupils to move in by September, 1921. Contrary to the usual idea that a one story plan, owing to the great area it covers, is a more expensive type to construct this type of building proved the reverse. This is undoubtedly due in the main to the following reasons; lighter foundations, simplicity of corridor space, lighter walls, saving of space by the omission of large stair walls, and the simplicity of heating layout.

The foregoing explanation is made to help the reader to realize the problems confronting the designers of the school and the natural bearing they have upon the results. After the sad experiences with previous buildings, it was necessary that the building should be fire-proof, so that in the final analysis of the construction and the conditions of the site on the top of a hill commanding a wonderful out-

look over Lake Minnetonka and the surrounding region, the building was constructed without a basement, except that necessary for the heating and ventilating plant. After the bids were taken it was found possible on one side of the hill to put another story below the main floor of the south end of the building. This was added to the building at a very small expense and will give extra space for expansion of the school at a later date. General construction of the building is as follows:

The entire main floor is a solid reinforced concrete slab upon light concrete foundation walls. Above this slab the main division of the floor was constructed of hollow building tile with white Portland cement, plastered on the outside and plastered, of course, throughout on the inside. The roof, being flat and having no requirements for space for machinery or pipes other than the conduits to carry electric wires, was built of wood, covered with an asphalt roof so that it is impervious to fire from the outside. The ceilings of the rooms were then covered with metal lath and plastered so that the fire hazard of this wooden roof is practically nil, and to all intents and purposes the building is fire proof.

In the design of the exterior and carrying out the design of the interior the architects fell back upon the principles of primitive American architecture untouched by the more recent developments in architecture throughout the rest of the world. The building follows the general architectural feeling of the Pueblos of New Mexico and Arizona. With its large interior

The problems involved in the Wayzata school exerted a marked influence both in design and construction. It disproves the notion that the one-story school is necessarily an expensive type.

A typical class room. In all study and class rooms the lighting is unilateral. Every class room where children sit or live has sun in it at some time of the day. Only the domestic science room is cut off from direct sunlight.

The school being largely a community center, a community room is provided near the entrance. Here the local organizations hold their meetings. When more space is desired, the space can be augmented by combining it with the gymnasium and domestic science rooms.

court and the low parapet walls every room in the building has ample lighting, and in all the class rooms and study rooms this lighting is unilateral. Every class room where pupils sit or live has sun in it at some time of the day, the only rooms which do not have sun light during the winter months being the domestic science room, and in our long summer days in Minnesota

the sun comes in there in the early morning and late afternoon.

Feeling that the school is largely a community center a special room was designed near one of the entrances as a community room, and this was pleasantly fitted up so that it would be attractive and desirable. Here the local woman's club and other organizations hold their meetings and

gatherings of the community take place. You will note from the plan that this is so arranged that the big combination auditorium and gymnasium and the domestic science room can be opened and utilized while the rest of the building is shut off, so that large gatherings and entertainments, games, sports, etc., are available to the community. As a matter of fact, the gymnasium is used every night in the week by classes of different ages and the school has taken a very definite part in the community.

The health of the children in the school is a very vital factor, and the severe winters of Minnesota, wherein for many weeks there is a chance of the weather being below zero, make the problem of heating and ventilating a most important one. Windows and doors cannot be opened. All entrances to the school must have vestibules, windows must be weather stripped and have storm sash, and all precautions taken to keep out the cold and wind. The general idea of heating the building was that under every window should be set enough radiation to maintain a proper temperature under practically all conditions. In addition to this was the installation of a very large plenum fan to supply fresh air to every room in the building throughout the working hours of the school. If all this air were taken from the outside in below zero weather and then heated and put through the different school rooms and exhausted into the outer air, no school board could afford to pay the heating cost for the winter's work, so that arrangements had to be made whereby the greater part of this air, sometimes as high as eighty per cent,

Built on a side hill, no basement is provided except for heating and ventilating plant. The slope of the hill permitted adding another floor for future expansion of the school. The building and plan follow the general architectural feeling of the Pueblos in New Mexico and Arizona.

would be recirculated through the school rooms. This meant that the air must be thoroughly washed and cleansed before being sent about through the school. The large fans send the air in two directions around under the corridors and from there force it up through the central partition walls and discharge it into the rooms near the ceiling. In every one of these rooms are outlets near the floor where the air leaves the rooms, and passes up through ducts into a large return duct over the corridor. From here it is returned to the fan room with proper automatic arrangements for taking in the fresh air supply and exhausting the foul air into the atmosphere according to the needs and temperatures. The result is a well ventilated building throughout with washed air and that degree of humidity which is necessary to the health of the pupil.

Being in a small village, where there was no central water supply and no central drainage or sanitation plant, a deep well was installed with an automatic electric pump delivering the water into pressure tanks, so that running water is provided for the air washer, the showers, the toilet fixtures, drinking fountains, kitchen, etc. All the sewage is handled through a large septic tank.

Minnesota has unusually definite requirements for the building of its schools and any school building in Minnesota must conform rigidly to the minimum requirements.

It might be said in closing that this Consolidated School serves as primary and high school and is operated along the general lines of what is known as the six-three-three system, six grades in the primary school, three in the junior high and three in the senior high.

After all the best test of a building is its use by the community and by the people in charge of it, and the excellent care taken by the Board of Education in the personnel of its teachers and the upkeep of this building and the grounds plays a large part in the ultimate success of the building.

Correction

The article on "Tuberculosis Patients as Health Educators," by Robert J. Wilson, M.D., which appeared in the March issue of THE NATION'S HEALTH was incorrectly attributed to the Bulletin of the New York City Department of Health. The article was published by courtesy of the New York Tuberculosis Association Bulletin.

Factors Relating to Suicide

DR. JOHN RICE MINER is the author of No. 2 of the Monographic Series of *The American Journal of Hygiene* (July, 1922) on "Suicide and its Relation to Climatic and Other Factors." The first part of the study, statistical survey, is summarized as follows:

(1) The general trend of suicide rates has been upward during the last century, but the higher rates especially tend to become stabilized. A factor in the upward trend is found in the decay of the group spirit. The European war has produced a sharp decline. The trend of suicide is in the opposite direction to the general death rate.

(2) Germany, France, Denmark, and Sweden show high suicide rates; the British Isles, Norway, Netherlands, and the south and east of Europe show low rates. These differences persist in the United States among immigrants, whose suicide rate is, however, much higher than that of home country. Japan and China have high rates, India low. In the United States, rates are lowest in the south, highest in the west.

(3) The maximum frequency of suicide occurs in May or June, the minimum in December or January. This appears to be an effect of weather *per se*.

(4) The lowest suicide rates are shown by the Greek church, followed by Roman Catholics and Protestants. Jewish rates have increased rapidly.

(5) Urban suicide rates are higher than rural.

(6) Suicide is more frequent among males in occidental countries, but among females in India.

(7) The suicide rate increases in general with the age, but with diminishing velocity. The female rate comes nearest to the male in adolescence.

(8) In general the married show lower suicide rates than the single or widowed. The divorced have high rates. Parents show lower rates than the childless.

(9) Suicide rates are low among farmers and others engaged in steady manual labor in the open air, while the professions (except the clergy and teachers), officials, capitalists, soldiers, innkeepers, and migratory laborers show high rates. Low economic status, when stable, is associated in general with low suicide rates.

(10) In western Europe mental disease is the most frequent motive of suicide. Both mental and physical diseases are increasing in importance as motives.

(11) The usual order of preference as to methods of suicide is hanging, drowning, shooting, cutting. Males show a greater disposition to hanging, cutting, and shooting; females to drowning, poison, throwing self from height, and asphyxia.

The second part of this study is based on the method of partial correlation. Analysis of the data of 174

American cities by this method fail to show any significant net correlations of suicide with mean per cent of sunshine, altitude, mean temperature, industrialization, or the number of negroes. Low, but possibly significant, correlations were found with low precipitation, density and general mortality, and high mean age. The correlation of suicide with the proportion of males was found to be $+ .41 \pm .04$.

General mortality was found to have no significant correlation with climatic factors, age, proportion of males of industrialization, but did show a low correlation ($+ .24 \pm .05$) with density and a high correlation ($+ .62 \pm .03$) with the proportion of negroes. A positive correlation was found between the proportion of negroes and precipitation and temperature but not with sunshine. Racial and economic factors probably influence this result.

"The fundamental factors underlying differences in suicide rates are probably (1) differences in strength of the group spirit, (2) adverse economic changes, (3) racial factors, (4) health of population."

Part three of this study is a bibliography of the subject containing the names of more than 350 authors.

A Town Score Card for Study Courses

The University of North Carolina Extension Bulletin for October 16, 1922 is devoted to an outline of town study for those interested in civic development. An accompanying score card for town studies allows out of a total of 1,000 possible points, 75 for sanitation and housing, and 100 for public health. The plan is particularly adopted for the use of communities desiring to conduct a self-survey.

The subdivisions listed under sanitation and housing are: inspection of congested and neglected areas, sanitary inspection of housing and factories, disposal of garbage and sewage, the supervision of building and construction, town-wide plans for cleanliness and filth prevention, and other factors.

Under public health are listed: a system of medical inspection service, adequate hospital services either in or near the town, food, meat, and milk inspection, child welfare services, laboratory services, and a statistical service for publicity and direction.

Good Health Habits Created Through Play

BY JAY B. NASH, SUPERINTENDENT OF RECREATION, OAKLAND, CALIF.

TO BRING out the close relationship between good health and constructive play, perhaps it would be well to tell briefly the aims of the Oakland Recreation Department. The major aims are universal physical efficiency, citizenship training and wholesome leisure-time habits; the provision of wholesome, healthful play for the children of the city, and the stimulation and guidance of adults in the use of leisure-time.

"Cooperation" is the watch word; it is due to cooperation with the Board of Education, primarily, that the progress of the play and recreation movement has been so rapid. At the present date there are fifty-four playgrounds operated in the city, thirty-four of these being school playgrounds, ten park playgrounds, the rest, tennis courts, golf course and lake playground. In 1907 there were two playgrounds in Oakland, in 1909, five, and on up the ladder until the present number has been reached. The school playgrounds are operated jointly by the Board of Playground Directors and the Board of Education. Expense for the maintenance of these grounds is divided as equally as possible between the two boards. The park playgrounds are maintained entirely by the Recreation Department, while the tennis courts are operated in conjunction with the Board of Park Directors.

The children reached in play programs each day numbered 35,000 in 1922, including the work of the physical education department of the city schools as well as after-school activities. The after-school group numbered 5,768. Recreational activities on Lake Merritt were attended by 170,422 persons. Permits were issued to 1,546 baseball teams. The number of baseball teams playing was 3,092.

With the first suggestion of spring, track takes hold of the boys. Each school has an inter-class meet; groups of schools have inter-school meets; and the big events are the city track meets—one for the younger and one for the older boys. Here each boy has a chance to try himself out against all the other boys of the city, both in track events and in marching. Each school is judged carefully in the posture parade, and the three schools getting the highest percentage of perfect posture in marching are awarded banners.

Girls' play days for the girls are planned and held at one of the larger park playgrounds. Special emphasis is placed on inter-class and neighborhood play days. Each program includes a posture parade, singing games, stunts, folk dances, baseball, volley ball, net ball, nine court basket ball, kick ball, long ball, bat ball and relays. Soccer and tennis are played where facilities are available.

In 1920 it was decided to abandon the old idea of one gigantic May day held at one of the city parks. Playgrounds were encouraged to give their own celebrations, and groups of playgrounds united in giving neighborhood May days. Last year from twelve to eighteen fêtes were held, many of the grounds uniting. Each one was a beautiful spectacle of child activity, enjoyed by the entire community.

STATISTICS FOR 1921-1922

	Number	Participants	Spectators
Pageants	4	5,000	40,000
May days	22	2,500	25,000
Play days			
Older girls	1	900	1,800
Younger girls	1	1,400	4,000
Neighborhood	28	8,000	5,000
Track meets			
Older	1	2,550	5,000
Younger boys		1,700	3,000
Neighborhood	25	7,500	5,000
Evening Recreation Centers	Permits Issued		
Outside organizations	840		58,650
Department clubs	664		45,000
Lake Merritt Activities:			
Adult Baseball Teams	1,546	34,000	350,000
Football Teams	130	3,850	200,000
Picnics		35,620	
Tennis courts	60	105,600	

Good posture, neatness and cleanliness are emphasized in the posture parade. Thirty-five inter-class play days were held including all girls above the fourth grade. Twenty-eight neighborhood play days and two city play days were also held.

In 1919 the Recreation Department definitely entered the industrial field for the purpose of stimulating the spirit of play among the workers in Oakland's various factories and plants. Volley ball was the opening wedge in introducing sports during

Play Day is the gala event of the Oakland school girls. Calisthenics, dances and games are the order of the day.

City boys play farmer at the Autumn Festival, a delightful picnic-day in Mosswood Park.

the noon hour. Basket ball and baseball have gained a foothold, while some of the industrial plants have installed tennis courts, and in one a miniature golf course has been prepared for the employees. Both men and women workers participate in these sports. Tournament cups have been presented for women's volley ball; baseball schedules are arranged, swimming classes organized, rowing crews trained for the annual regatta, under the supervision of a special director for the women workers. A sports carnival is given each year in the municipal auditorium with all the plants represented for competitive games. A girls' auxiliary to the Industrial Athletic Association of Greater Oakland has been formed. Dancing parties are given in the community club houses during the entire year. Much has been done in this line to create wholesome leisure-time habits as well as a better spirit among the workers.

Sixteen baseball fields are available each Saturday afternoon and all day Sunday from 9:30 in the morning until 5:30 in the afternoon. Teams of working boys and men keep these diamonds filled to capacity on all the clear days. Permits to use the grounds are given out in the office of the Recreation Department, each team being allowed two hours' play. About 1,546 permits were given out during the past year, with approximately thirty-four thousand men and boys enjoying the great "national game."

We are very fortunate in having a

beautiful lake with an area of 160 acres in the very heart of the city. Here the children and adults of the city are encouraged to use for rowing the forty-two whaleboats which are available. Crews are organized on many of the playgrounds, and there is practice once or twice a week preparatory to the regatta which is given once a year. The Oakland Women's Rowing Club is an old organization open to all Oakland women. It has four active crews entering the regatta. Approximately 170,422 women and children used the facilities at the lake last year.

A municipal golf course is in the process of preparation. All the grading has been done and the ground seeded, and play will begin in the spring. It will be open to the entire city, with each player paying a small monthly membership fee that will make the course self-supporting. A club house with lockers, showers and lunch facilities is planned, and an over-night camping ground is contemplated. The course will consist of eighteen holes at the present time with possibilities for adding eighteen more in the future.

In the way of camping facilities already established, Oakland has a mountain camp in the Sierra Nevada Mountains. This is known as the Oakland Recreation Camp and is located on the middle fork of the Tuolumne River, 157 miles from Oakland in the Stanislaus National Forest, Tuolumne County. The camp is run on a cost basis, \$23.25 for adults and \$15.65

for children for a two weeks' vacation—this including board, lodging, and transportation. A water supply, permanent buildings for dining, office, cook house, store houses, a sanitary system and tent platforms have been put in, and the guests are housed in canvas tents. Swimming, fishing, hunting, hiking or "just plain loafing" are all possible. Groups of children under the supervision of capable playground directors, together with families from all parts of the city visited the camp and enjoyed a good mountain vacation. Last summer 1,835 children and adults of Oakland visited the camp for one, two or more weeks. A Save-For-Vacation campaign is organized every winter to encourage children and adults to save for a summer vacation somewhere.

An In-town Camp is carried on in the hills back of Oakland, where over-night hiking parties and week-end camping trips are enjoyed. Campers carry their own blankets and other equipment, but the camp is well provided with drinking water, fireplaces and latrines. The new golf course is ideally situated as a hiking objective from Oakland and it is planned to provide elaborate over-night accommodations there for campers and hikers. It is hoped to have a girls' camp also, maintained along the same lines as the Boy Scout camp in the foothills of Oakland.

There are numerous open-air fireplaces located in the park playgrounds of the city where coffee pots, weenie sticks, spoons, tin cups and other conveniences are furnished. One of the parks, Mosswood, is equipped for large parties. Tables and benches for about five hundred are available. Here county organizations hold their reunions, Sunday schools hold picnics, and numerous other large groups meet.

Launch parties up to one hundred can be accommodated on the lake, where launches and suppers may be arranged at the tea room. There is also a tea room in Mosswood Park. At both places lunches, suppers, and banquets can be arranged.

Nowhere is hiking more popular than in Oakland. Young and old take part in healthful and pleasurable trips to the hills in the bay district. Trips are taken by groups of children from the playgrounds and very often a community hike is planned for the people living around the playgrounds. The Contra Costa Hills Club is an organization that gathers into its membership many hiking enthusiasts, with the Recreation Department co-operating. Outdoor clubs for women are active on

four of the park playgrounds, while tennis has become very important as a "hold over" sport both with children and adults. Much stress has been put upon this game. Every child in the city above the fifth grade has been reached in the past year, with instruction given by two special directors. Tournaments have been arranged and played off, clubs have been formed, and everything possible done to encourage young and old to learn the game.

With the growing stress which is being laid upon the axiom "exercise is the price of life," the importance of the vigorous outdoor exercises of the playground increases. Our country is in danger of becoming a people of "button pushers and lever pullers," and it is a common trait of all men to be just as lazy as circumstances will allow them. With additional emphasis upon these vigorous outdoor activities we may possibly find in the years to come a decided reduction in children's disorders. It may so greatly reduce these disorders that we will not find necessary all our elaborate corrective program.

The Question of Garbage Disposal in Boston

The question of garbage disposal in Boston has been a controversial one for many years. The present practice of reducing the garbage and dumping the other wastes on land was severely criticized by special commissions in 1908 and 1910 but when the old contract expired in 1922 a special commission of which Health Commissioner Hoodward was chairman, recommended that the city enter into another ten year contract with the garbage reduction company. A recent report by Mr. George A. Johnson¹ indicates the present system in very vigorous terms emphasizing the practical difficulties involved in the separate collection of garbage, ashes and rubbish and the nuisance created by the reduction plant on Spectacle Island. He believes that the present collection costs are unnecessarily high, particularly in those districts where collection is carried on by the city itself rather than by contract, and he strongly recommends that the city come to some agreement with the reduction company by which the contract can be broken. The alternative process which he proposes is the construction of eight incinerators of the type which has proved so successful in Montevideo and the burning in

these incinerators of mixed refuse with the use of power for electric lighting. The figures given in Mr. Johnson's report show slight discrepancies, but as we understand them the table below indicates the collection and disposal costs under the proposed plan as compared to the present system.

	Proposed Plan		Present	
	Gross	Net	Plan	Saving
Collection..	\$54,000	\$64,000	1,326,000	461,000
Disposal ..	\$64,000	\$66,000	454,000	\$8,000
Total	1,178,000	1,230,000	1,780,000	549,000

Mr. Johnson believes, as these figures indicate, that the cost of collection can be very substantially reduced by having it all done by contract and by shortening the hauls through the construction of eight destructor plants. He also believes that incineration will prove more economical than the present disposal system, but this later conclusion rests, as will be noted, on the assumption of a very substantial return from the use of the steam produced, a return which has never been realized in any American city.

The Montevideo plant has been recently described in a special report by George F. Stall to the Common Council of the city of Milwaukee under date of September 6, 1922. It is a high temperature incinerator of the "Balmer" type which differs from other incinerators in the general simplicity of arrangement and in the provision of special storage bins through which the forced draft is conducted to eliminate the possibility of odors. The Montevideo plant during its first year of operation consumed 151 million pounds of garbage and refuse at an estimated cost of \$0.53 per long ton and with marked freedom from nuisance.

Examination of Food Handlers in Dallas

An ordinance of the city of Dallas, Tex., requires of every person who handles food or drink of any kind a health certificate showing that such person has been examined by a reputable physician and found free from communicable disease. A Wassermann is required once a year if found negative, otherwise more frequently. Smears for gonococcus are taken whenever necessary.

According to Dr. W. T. Davidson, director of Public Health, "A separate budget is made for the food handlers' unit, which is under the division of communicable diseases. A fee of one dollar is required for the complete examination which is just about enough to bear the expenses, there being one doctor, one nurse, and one clerk."

A note in *Public Health Reports*, March 2, 1923, called attention to a habeas corpus proceeding in which the Court of Criminal Appeals of Texas held valid the ordinance under which this work is carried on. The person who sought the writ of habeas corpus was the proprietor of a meat market who had been convicted for having worked in the establishment without having a health certificate.

Tennessee Reorganization Bill

Bill No. 183, known as the Reorganization Bill was passed by the Tennessee legislature in February. By its provisions the State Board of Health with its secretary and executive officer was abolished and in its place has been created a Department of Public Health with a Commissioner at its head. Under the Commissioner is a Superintendent of Vital Statistics, Superintendent of Rural Sanitation, Bacteriologist and Sanitary Engineer. The Maternity and Child Welfare and Venereal Disease Control Divisions were omitted from the organization scheme but it is probable that both of these will be reinstated when the legislature takes up the miscellaneous appropriation bill during the second half of its session.

Chicago Dental Services

Underwood & Underwood

The Chicago Dental Society is at last getting under way the extended program that its men of vision have been working out for the past several years. At Cook County Hospital a five-chair all-day clinic will be established to take care of the 6,500 children going through Cook County Hospital every year, and the thirty thousand children who pass through the juvenile court. No other effort in prevention and cure of the ills that come from neglected teeth has been undertaken on so thorough a basis or on so wide a scale.

1. Abstracted in the Boston City Record, Saturday, March 3, 1923.

Physical Educators Hold Annual Convention

THE 30th Annual Convention of the American Physical Education Association was held in Springfield, Mass., April 11-14, 1923. The first day was given over to registration and inspection trips. Busses were provided to transport the delegates to local high schools, junior high schools, elementary schools, and open air schools, whose equipment and methods of physical training were inspected by many of the visitors. The trip to the Springfield Y. M. C. A. College proved popular.

The first general session of the association was held in the Springfield Auditorium, Wednesday Evening. Mayor Edwin F. Leonard extended a welcome on behalf of the city and Superintendent James H. Van Sickle on behalf of the local schools. Dr. J. H. McCurdy, director of normal courses in physical education, International Y. M. C. A. College and secretary-treasurer of the Association, then introduced Pres. Carl L. Schrader, state director of physical education in Massachusetts. President Schrader said in part:

Education the world over is in a turmoil and of new theories and systems there is no end.

Out of the whole, if one reads correctly, there is one general objective, one general hope which permeates all, and that is that the individual shall have equal opportunity to reach his possible goal, rather than that all have an equal chance for a common, often an impossible goal. The road to this goal should at all times lie within view of the realities of life, making contact all along the way.

The junior high school, which is a remarkable reaction in educational lines, has opened up a great opportunity for the physical line of education. How prepared are the teachers to make this necessary contribution to the junior high school? A great many places where the junior high school has taken root, have unbalanced programs. Either they have put into effect the evils of the high school athletics, or have reverted to the stilted types of physical education in the lower grades. These places have not yet heard of well balanced physical education program.

In the colleges there is an unfortunate division between the major and minor sports. Any sport that is not a major sport is considered a sort of "also sport." Inasmuch as none of the team sports last much beyond the school or college career, nothing but the minor sports so-called, remain for the professional man.

Every distinct type of activity attracts a distinctive type of individual. The football type of boy, for instance, is rarely found among the gymnast and the other way around. This is true of nearly all kinds of sport.

In the minor sports there is a great deal of the fundamental exercise for the development of muscle to be used either for grace or skill. All specialization in physical education must be based on the generalization of both, to be intelligent and to be safe. We must determine what is the natural activity of a pupil and do all in our power to develop him in this line, still maintaining a well-balanced physical development.

The second day was opened with a general session on the topic of organic efficiency. Prof. E. C. Schneider of Wesleyan University spoke on "Physical Efficiency and the Limitation of Measurements of Efficiency." He spoke of the present wave of interest in measuring the mental and physical capacity of mankind and of the great difficulty in getting tests that were real measures of fitness for muscular exertion, and not a measure of some byproduct of fitness. Prof. Schneider continued:

Different jobs will require different degrees of fitness, but so far as the workers of each kind are concerned the work must be a "normal load" for them. I believe that our best definition of fitness is found in our understanding of a normal load, a crest load, and an over load. With a normal load the oxygen account balances.

With the crest load it still balances but the adaptive mechanism, the breathing, the circulation, the blood, and the unloading of oxygen are all working at top-notch capacity and are unable to increase further the delivery of oxygen; and with an overload the oxygen account does not balance, it is overdrawn. It is obvious that for the steady work of day after day such over-drafts are impossible. He who desires to reach the maximum crest load must resort to physical training.

In speaking on the "All or None Theory in Relation to Muscular Exercise," Percy G. Stiles, Professor of Physiology at Harvard discussed the newer conceptions of the nature of nervous stimuli and of the possibility that there are relatively favorable and unfavorable frequencies of vibration in the number of fibers brought into action. Since we are no longer permitted to think of any intensified outflow of nervous impulse from the brain when struggling against fatigue we must think of a diffuse outflow, which conception is supported by the spread of activity to muscles other than those we seek to control.

The closing address of the session was on the subject of the "Relation of Internal Secretions to Physical Efficiency." Dr. Frank A. Hartman of the Physiological Laboratory, Buffalo, N. Y., discussed the part played in

muscular activity by the secretions of the pituitary, thyroid and adrenal glands.

The Public Schools' Section, the College Directors' Section, the Industrial Section, and the Women's College Section held divisional meetings in the afternoon.

The Annual banquet of the Association was held at the Hotel Kimball on the Evening of April 12th. Dr. Stephen H. Olin, acting president of Wesleyan University was the principal speaker. He said in part:

American colleges and universities fifty years from today will expect a student who has completed his course of study to be a real scholar rather than a "learner of some particular science or the art of making a living," according to the speaker.

Colleges have scrapped the scholar, but happily they have created the athlete. I hope that sometime the colleges are going to reassert themselves as moral and mental guides in our country and require certain standards of scholarship and certain subjects for instruction. I am not opposed to the program of athletics in colleges and universities, but believe that scholarship should not be lost sight of. Athletics have done great things for American educational institutions, one of the most important of which is establishing more friendly relations between neighboring colleges.

Courtesy and civility will be developed in collegiate athletics as the years pass. It is to be deplored that members of two college teams, in the middle of a contest, occasionally resort to discourteous language. Physical education instructors are beginning to insist on a more "gentlemanly and scholarly" attitude on the part of their pupils in athletic contests.

Following Dr. Olin's address last night, Dr. Dudley B. Reed, physical director at Chicago University, presented Dr. James H. McCurdy, dean of the physical education department at Springfield College, a gold watch in a specially engraved case, in recognition of the services of the Springfield man, as a member of the Council of the Association during 1922.

At the general session held Friday forenoon the topic was Nutritional Efficiency. Prof. G. B. Affleck of the International Y. M. C. A. College summarized the examinations of eleven thousand children in the public schools of Springfield who have been examined six times during the last year and a half. Some of the conclusions drawn from this study at its present stage are:

Despite the effects of the height-weight tables they are of value in detecting the vast majority of undernourished children.

The height-weight tables give no indication of the causes of malnourishment in the underweight groups.

During the months of August to November inclusive, pupils usually gain half or more of their annual increment in weight.

There is a very slight gain, or maybe a loss in weight during April, May and June.

There is a decreasing percentage of pupils in A and B groups, both boys and girls in the upper grades of the elementary schools.

There is practical equality in the nutrition rating of the two sexes.

Pupils of Assyrian, Hebrew, Greek and Italian parentage are the nationalities having the highest percentages in nutrition classes A and B.

Pupils of Irish, English, American and Scotch parentage are the four lowest in percentages in groups A and B.

The school with the highest average nutritional rating has an Italian enrollment of 78.6 per cent.

The average percentage of pupils of Springfield schools in nutritional groups A and B, according to the Emerson scale is: September, 1922, 71.1; December, 1922, 79.6; March, 1923, 78.0, or an average for the three consecutive surveys of 76.2. Emerson's estimate for the country is 66.0 per cent.

The second paper of this session by H. C. Sherman, Professor of Food Chemistry at Columbia, dealt with "Nutrition and Vigor." The speaker grouped the chief types of food according to their nutritive characters as follows:

(1) Breadstuffs and other grain products—economical sources of energy and protein but not satisfactory in their mineral and vitamin content.

(2) Sugars and fats—chiefly important from the nutritional standpoint as supplementary sources of energy, although some fats are also important as sources of the fat-soluble vitamin.

(3) Meats, including fish and poultry—rich in protein or fat or both, but showing, in general, the same mineral and vitamin deficiencies as do the grains and breadstuffs.

(4) Fruits and vegetables—varying greatly in their protein and energy values, but very important as sources of mineral elements and vitamins.

(5) Milk—important as a source of energy, protein, mineral elements and vitamins; the most efficient of all foods in making good the deficiencies of the grains and in insuring the all-round adequacy of the diet.

Prof. Sherman again urged that it must be more widely recognized that a full quart of milk a day is required by the growing child in order to support a fully normal rate of growth with the best development of bones and teeth.

The concluding speech of the session was by Dr. George E. Dawson, of the Springfield Y. M. C. A. College. The speaker showed that physical education should become a means of developing a cultured intellect. He further stated that "not only the masses

of the people, but the educated classes, do not think of physical education as having much to do with training the mind, like other departments of education in the public schools and colleges." Physical education may train the mind "by sensitizing the nervous system so as to bring the life consciously into more intimate relationship with its environment; by helping to integrate the factors of consciousness so as to make thinking more effective, and by bringing the body under more perfect control of the mind, and so accomplishing a more perfect control and mastery of the surrounding world."

Dr. Dawson told of studies carried out on the students at the Springfield Y. M. C. A. College for the purpose of determining any possible correlation between physical activity and primary mental functions. If we think of intellect not in terms of information or of acquired culture of any kind, but rather in terms of those primary qualities of intellect that are revealed in the ability to integrate sensation, mental association and action, such ability can be analyzed experimentally by means of tests of reaction time. Tests of 350 of the Springfield college men show that they present a better sight reaction (22 per cent), a better touch reaction (12 per cent), and a better auditory reaction (8 per cent) than does the average man. The tactile and kinesthetic sensitiveness of the physical men was also found to exceed that of the secretarial students. The hand control of the students was found to be nearly three times as accurate as that of the average man and the physical students made on the average less errors than the secretarial students.

In the afternoon the Women's athletic, the therapeutic, the Y. M. C. A., and the playground sections held meetings. During the noon recess the industrial section held a round table luncheon and discussion at the Hotel Highland.

Friday evening was given over to demonstrations of stunts, dancing, tumbling, gymnastic drills, and apparatus work by students of the public schools; an exhibition by the gymnastic team of the Y. M. C. A. College; and a demonstration by the Springfield Y. M. C. A.

The last session, held on Saturday morning, April 14, was in charge of the Athletic Research Society, President Chase presiding. The first speaker was Dr. Ledyard Sargent of the Sargent School, Cambridge, who gave an illustrated talk on the "Sar-

gent Test." Briefly, the Sargent test consists of a simple jump, the height above the floor attained by the top of the head can be easily measured by several simple devices. From this height is deducted the standing height of the individual, giving the so-called "jump" which is the measure of the test. It is not a vascular test as it requires but a second to perform it. It is a neuromuscular test and the ability displayed in it by any individual depends on strength, speed, and driving power—neuromuscular efficiency. There is no possible way of "beating" the test? Slowness is penalized. The test involves a large number of the muscles of the body, is interesting to boys and girls, and has a wide range of applicability. Various investigations carried on for a period of more than two years seem to show that above the high school age the jump is independent of both height and age. No correlation is found between the height of jump and measurements of various parts of the body, and tests on feeble-minded children indicate that mental age is closely related to performance.

Dr. R. K. Atkinson of the Russell Sage Foundation, in speaking on the "Effects of Recreations and Athletic Activities on Subnormal Groups," presented some of the findings of Dr. A. P. Way relative to a survey of eight thousand New York City high school boys. Their performances in various athletic and motor efficiency tests had been analyzed with reference to height and age. The possibility of determining standards of performance for the average, above average, and the under average boys was considered.

While individualization must characterize corrective work in subnormal groups, as progress is made it becomes possible to form classes. The recorded work of representative types and representative groups will gradually evolve standards of practice in this important field.

The 1923 convention of the American Physical Education Association was officially closed with a meeting of the Council at which it was voted to hold the next annual convention in Kansas City, Mo. The council took official action recommending that athletic instructors of girls' and women's colleges take measures to train all of the students in physical culture before attention is devoted to developing varsity teams for intercollegiate contests. The body also approved the resolutions drawn up by the committee on track athletics for girls and women, expressing the same opinions regarding intercollegiate sports for women.

Camouflage in Soft Drinks

THE people depend too much on their eyes and not enough on their intellect in the selection of their beverages, states E. J. Lea in the report on the Bureau of Foods and Drugs in the twenty-seventh biennial report of the state board of health of California. The elimination of artificial color from soft drinks, would, he thinks, solve the whole problem so far as the public is concerned and he recommends amendment of the food laws so that this will become possible.

The report goes on to say with regard to soft drinks:

At the present time there appears to be far more violation of the food law in the line of soft drinks than in any other class of materials under the jurisdiction of the Pure Foods Act. It is true that a certain amount of improvement has been made with regard to adulteration and mislabeling of soft drinks since the food law became effective in 1908. Harmful colors, harmful flavors, and saccharine have been practically eliminated, but by far the greater proportion of soft drinks consists either wholly or largely of imitation concoctions which masquerade as fruit drinks.

The labels of these products are usually designed in such a way that the name of a fruit or the picture of fruit is the most conspicuous part of the label, and frequently they are the only features which catch the eye of the consumer. In some cases, by carefully scrutinizing the label, further information may be found to the effect that the article contains many substances which are entirely foreign to fruit and the analysis of the product may disclose that little or none of the fruit is present.

It is not alone the labels which are deceptive, but extensive advertising, usually more deceptive than the labels, is conducted by the use of bill boards, placards, circulars, newspapers, etc. For example: A beverage labeled "Orange Squeeze" was advertised on bill boards by the use of a picture of a hand squeezing orange juice into a glass. This design prominently featuring fruit was made very attractively by appropriate colors and the natural inference from seeing the advertisement would be that the product consisted essentially of orange juice. The facts in the case are that the fruit drink consisted of citric acid, sugar, water, orange oil flavoring from the peel of the orange, and the entire mixture was colored with coal tar dye in imitation of an orange juice product.

A beverage labeled "Orange Crush," which has also been extensively advertised, was originally composed of ingredients similar to the above. More recently a small proportion of orange juice has been included, but the amount is so small that the finished drink contains less than one-half of one per cent of any product from the orange. The original labels for the

so-called "Orange Crush" contained no information to the effect that the article was almost entirely an imitation. The newer labels, however, declare in small print the various ingredients present, but the advertising of this article on bill boards, placards and in newspapers still carries the idea that the drink is made from oranges.

A beverage labeled "Orange-Nip," "Prepared from Pure Orange Juice," has recently been analyzed by this bureau and found to consist entirely of sugar, water, citric acid, orange flavor and orange peel, coal tar dye and less than one-half of one per cent of orange juice.

Numerous other examples might be mentioned, such as "Orangade," "Cherry Smash," "Grape Punch," etc., which are largely, if not entirely, imitation products.

This subject may seem of minor importance, and yet in the aggregate it has been estimated that the annual expenditure for these beverages in the United States is over five hundred million dollars. The industry has swelled in a few years to enormous proportions. Formerly confined to the small local soda-pop manufacturer and circus lemonade vendor, it now supports numerous large plants, many of which do a national business on an extensive scale.

From the standpoint of healthfulness, toning qualities, and vitamins, soft drinks may be classified in two groups, namely, those which are made of fruit or fruit juice, and those which are not. The soft drinks which really consist of fruit juice are exceedingly scarce. The majority of the drinks are not even "near-fruit" drinks.

Pure fruit juices from certain fruits, such as grapes, loganberries, apples and pineapples, are bottled commercially. These genuine fruit juices are generally carried by grocers, for family trade, and they may also be had in many places, such as dining cars, buffets, hotels, etc., where drinks are dispensed; but the business in the genuine fruit drinks is very small as compared with that in imitation drinks.

There has been a tendency during recent years to label as true fruit drinks certain preparations which contain a minute amount of highly concentrated extract or essence derived from the fruit; the other ingredients, forming the bulk of the drink, being imitation products. These fruit essences do not contain the healthful and nutritious properties of the fruit; they are simply the smell, and their use does not justify the labeling of the drink as a true fruit drink. Many of these concentrated true fruit essences are fortified with imitation essence derived from synthetic ethers.

Some of the so-called fruit drinks are first manufactured in the form of a concentrated syrup, containing a small amount of fruit juice and heavily loaded with coal tar dye. To these syrups the bottler adds an acid solution and then dilutes the mixture many times with water. When these

drinks are finished for consumption the small amount of fruit juice present is diluted to such an extent that it has practically no bearing on the quality or value of the drink. These products, as usually manufactured, contain such a minute amount of fruit juice in the finished drink that they do not justify the labeling of the concoctions with the name of a fruit.

Progress is being made in the manufacture of soft drinks, from genuine fruits without the addition of acids or coal tar paint to imitate the fruits. The University of California has experimented along these lines and at the present time has prepared for exhibition purposes soft drinks made from strawberries, loganberries, raspberries, grapes, oranges and pomegranates.

These beverages are extremely palatable, have plenty of color from the natural fruit, and, above all, they are healthful and nutritious, and their qualities are far superior to those of the imitation products.

It has been fully demonstrated that soft drinks can be prepared commercially from the fruit itself without any imitation ingredients, and that they can be manufactured at a cost which is not prohibitive.

California has an abundant supply of many different fruits, and it seems entirely reasonable and practicable to utilize more of these in the manufacture of soft drinks. Furthermore, the general use of soft drinks made of fruit instead of the imitation products would greatly benefit the health of consumers.

The pure food laws were designed to protect the public and the honest manufacturers. Our experience in the manufacturing, labeling and advertising of soft drinks seems to indicate that the public is not properly advised as to the nature of the soft drinks which they purchase. Artificial color, which, in the case of soft drinks, is usually coal tar dye, seems to be the principal agent that contributes to the deception. Many manufacturers have told us that they could not sell their beverages at all unless they used artificial color and, in fact, some of them have said that they could not continue in business if they did not use artificial color, because the consumers would not buy the drinks which did not have color.

In other words, a drink labeled with a fruit name and composed of citric acid, sugar, imitation flavor and water, without artificial color would not be accepted by consumers, but the identical mixture with the addition of a little artificial color would be favorably received. We are also advised by manufacturers that the word "imitation" on the label of soft drinks practically kills the sale of that drink; while the identical preparation without the word "imitation" on the label would have a normal sale.

Affiliation of Grinnell, Penn and Central Colleges, (all of Iowa) with the school of nursing of the state university, was urged in a recent conference of officials representing the institutions concerned.

Consider the Toothpick

THE toothpick is a small pointed instrument usually made of wood or quill but sometimes of ivory, silver or gold. It is designed to dislodge fragments of food from the dental interspaces. The elegant decree is that it should be employed in private or that when imperatively necessary the operation be performed behind the seclusion of a napkin after appropriate apology.

Some toothpicks are individual, some are enclosed in sterile envelopes but the garden variety is generally placed in an open dish whence they may be extracted post-prandially by diners whose regard for comfort transcends the dictates of good breeding. There are many circumstances of life which are unavoidable but a toothpick is one's own fault.

Anything which will assist in keeping the mouth clean and in preventing dental decay is a useful sanitary adjunct and as such toothpicks in themselves are more to be pitied than blamed. As ordinarily set out on the restaurant cashier's desk, they may, however, become the vehicles of transmission for micro-organisms to such an extent as to more than counterbalance their good effects.

Who has not seen the open saucer of naked toothpicks into which a hand which has just wiped a mouth is plunged! It is well nigh impossible to pick up only one toothpick from the little pile in the saucer. Hence two or more are abstracted and touched by a hand which may be smeared with mouth secretions. One toothpick is retained and the others scrupulously dropped back into the dish. Another customer hurries up blowing his nose. Hastily thrusting a very dirty handkerchief into his pocket, he pays his bill, thrusts his fingers into the bowl and fumbles for a toothpick. Another wipes an eye and reaches into the dish and another puts his cigarette between his lips, which he unconsciously touches with his fingers, and then paws the toothpicks. And so it continues until every toothpick has been touched at least once.

When it is considered that the toothpick goes straight from the dish to the mouth, there to be forced between the teeth, there usually to inflict trauma and perhaps to be finally chewed, it is seen that any living pathogenic organisms on its surface have been afforded on excellent opportunity of gaining entrance to the body and it is conceivable that in this way

influenza and similar infections may be spread.

The remedy is both obvious and simple. Prevent the display of toothpicks in the manner described above. Perhaps after all the polite interdiction against toothpicks in public is a measure of hygiene as well as manners. If so it is to be commended and the custom spread.

Special Instruction for Industrial Physicians

The need of special courses for the instruction of physicians who are appointed to look after the sick in large commercial chemical houses is brought out by a Paris correspondent to the *Journal of the American Medical Association*. He holds that the "factory physician," before taking on the responsibilities associated with the employment and conservation of labor, should acquire special theoretical and technical knowledge in the field of occupational diseases and industrial toxicology.

It will not be necessary to create in the medical schools special chairs for this purpose. All that will be needed will be to adapt certain courses of instruction to this new function and to assign to the professors responsible for these courses the needed collaborators and the means of carrying out this adaptation. The main thing would be to amplify the instruction of industrial toxicology and to develop further our knowledge of occupational diseases. The instruction, however, should not be confined to theoretical lectures on these subjects, but should include practical demonstrations, says the writer.

Professors of medical jurisprudence are, for the most part, members of the councils on public health. They might easily use the influence that goes with their official positions to secure from manufacturers the necessary authorization for their pupils who intend to become factory physicians to visit chemical plants and study conditions at first hand. Students would thus gain a practical experience that would be exceedingly valuable to them, the writer concludes.

Sanitation of Tourist Camps

By ALBERT H. JEWELL, CHIEF ENGINEER, DIVISION OF WATER AND SEWAGE, KANSAS STATE BOARD OF HEALTH, LAWRENCE, KANSAS.

WITH the increased number of automobiles and the growing mileage of good roads, there has been an increase in tourists throughout the entire country and, with the tourist, has come the problem of providing satisfactory camping places. The problem is by no means a standard one and will be found different for each section of the country. For instance, some of our northern states will have a very large number of summer resorters, while in Florida the tourist season is in the winter. In either of these cases, the tourists come with the idea of staying in the camp and making it headquarters for several days, possibly for weeks. In Kansas the problem is entirely different; there is neither natural beauty nor fine climate to appeal to the resorters. However, there are a number of highways which form a link between the east and the west; traversed by tourists bound either for the western coast or the eastern. In the majority of cases these tourists desire to stay over night and be on their way again the next day.

In contrast to this, there are some

who are neither going nor coming, but are using this means to save paying rent, moving from one location to another—wherever they can find a means of livelihood.

Some may consider that it is not the duty of the city to provide facilities for camping. But from the standpoint of public health and protection to the citizens of the community itself, it seems that this is the best way in which to control the situation. If sanitary facilities are not afforded, it will mean that the tourists will camp here and there like gypsies; and the result will be insanitary conditions and the danger of fly infections, to say nothing of other nuisances. The small cost of providing these features can be taken care of by any city, without placing a burden on the tax-payer. In some cases, the business men of the city have financed the proposition, feeling that even from a business standpoint the camp is a good investment.

In considering the tourist camp, the first thing naturally is that of location. If possible, the camp should be located where it will be accessible to

the municipal water and sewerage systems. The municipal water supplies of the state are analyzed at least twice a year by the state board of health and therefore are kept in very good condition and can be used by tourists without any danger of water-borne diseases. If the toilets are connected to the sewer system, this removes the grave danger of fly infection and possible contamination of water supplies. The location should be well drained and where it will not be a nuisance to surrounding property owners. In some cases, the surrounding property may be deleterious to the camp.

If there is no municipal water or sewerage system, it will be necessary to resort to the use of a private well and sanitary fly-proof privies. The well should be properly protected against surface drainage and should be located above any source of contamination and as far away from the privies as possible. Water from private wells should not be used until after it has been analyzed and approved by the state board of health. A tourist should regard all such sources of supply as dangerous or questionable and should either boil the water or treat it with sterilizing tablets for that purpose.

It is very often found that one part of the municipal park can be devoted to a tourist camp, thereby making the water supply and toilet facilities serve a double purpose.

Garbage and trash should be kept in covered, fly-proof cans and removed daily to some remote spot where it can be either burned or buried.

It is impossible to construct a tourist camp that will not need daily care. The best that can be done is to build the camp in such a way as to make this maintenance as easy as possible. In general, floors of buildings should be made of concrete and properly drained and this will facilitate the flushing and scrubbing to keep them in a clean condition. All openings should be screened. Plenty of placards should be placed around the camp directing the tourist as to water supply, toilets, what is to be done with trash and garbage, and where wood can be obtained, and regulations regarding the conduct of the camp. The attendant should also be vested with power to regulate the length of stay. It is not altogether advisable to set a hard and fast rule since in some cases there may be a very good excuse for a tourist to remain several days, while in other cases there might be sufficient reason for not allowing the tourist to stop at all.

There are a number of things which add to the convenience of the tourist not absolutely essential but which can be provided at a minimum expense, such as tables, benches, stoves, shelter houses, sinks, electric lights, wash tubs, clothes lines and shower baths. If flies can be prevented by the proper disposal of waste, garbage, and sewage and if the water supply can be protected from contamination, the camp can be maintained in a sanitary condition with a very reasonable amount of care.

Tourist Camp Sanitation

At a regular meeting of the Kansas State Board of Health, held in the office of the Secretary, Topeka, on February 15, 1923, and under the authority of section 10122 of the General Statutes of 1915, the following regulations relating to tourist camps were unanimously adopted and ordered printed in the official state paper:

Sanitary Regulations of Tourists' Camps.

(1) All camps shall be in charge of an attendant whose duty it will be to keep the camp in a sanitary condition at all times.

(2) All camp sites shall be well drained.

(3) An adequate supply of potable drinking water shall be provided on all camp grounds. Water from wells other than a public supply shall not be used until it has been approved by the State Board of Health.

(4) Modern flush toilets shall be provided where sewer connections are possible.

(5) Where sewer connections are not possible, sanitary, fly-proof privies, approved by the State Board of Health, shall be provided.

(6) All garbage and refuse shall be stored in metal cans with tight covers and shall be removed from the premises and disposed of daily.

(7) Garbage and refuse shall be disposed of by incineration or burial.

(8) Those in charge of camps shall make and placard such rules and regulations as are necessary to govern the use of the camp and keep it in a sanitary condition.

(9) Inspections of tourist camps shall be made under the direction of the State Board of Health as often as practicable and a report of findings made to those in charge. If the recommendations are not carried out and the camp is found in an insanitary condition upon a second inspection, the camp will be declared a nuisance to public health and ordered closed, and shall not be reopened until such time as the recommendations have been carried out.

I hereby certify that the above is a true and exact copy.

Given under my hand and seal the 16th day of February, 1923.

S. J. CRUMBINE, M. D.
(Seal) Secretary and Executive Officer.

Editor's Note.—Under date of February 14, 1923, the author of the preceding article made a report on Tourist Camp Sanitation to the members of the Kansas State Board of Health, with the result that on February 20, 1923, the above notice appeared in *The Topeka Daily Capital*.

Health Conditions in Russia

Reports by Dr. Siemashko, People's Commissary for public health of the Soviet republic, before the Health Committee of the League of Nations at Geneva in January indicate that the public health situation in Russia is still a gravely critical one. Over one million, three hundred thousand cases of typhus fever and the same number of cases of relapsing fever were reported for the year 1922 and, in addition, malaria of a very severe type is spreading. The tuberculosis rate in the city of Petrograd was 370 per 100,000 in 1918, 510 in 1920, and 360 in 1921. The infant mortality rate in Moscow was 330 per 1,000 births in 1919, 225 in 1920, and 265 in 1921.

The Barrel Loader as a Safety Device

Heavy barrels can be loaded in tiers in box cars without danger of their rolling back, by means of a device developed by the Walworth Manufacturing Company of Kewanee, Illinois. As seen in the illustration the loose end of the skid rests on the first tier of barrels in the car, making it unnecessary to fasten this end. The hoist is raised by a two and one-half horse-

Showing the hoist in loading position.

power motor and the barrel rolls into the car. The hoist is equipped with upper and lower automatic stops, making it unnecessary to employ a skilled operator.

The previous method of loading barrels was to roll them up the skid by hand. Sometimes, with heavy loads the barrel would slip, causing injury to the loading crew. Although designed primarily as a safety device, this hoist has proved to be a great time saver as well. It has received favorable comment in the *National Safety News*.

Second Child Health Demonstration

The Child Health Demonstration Committee of the American Child Health Association is receiving applications for the second community to benefit from the Commonwealth Fund appropriation for three child health demonstrations. Fargo, North Dakota, has been chosen for the first demonstration.

The general purpose of the demonstrations is to help the communities chosen in every effort to save the lives of mothers and babies, and to see that its boys and girls develop into strong, sturdy citizens with a wholesome outlook on life. Every phase of child life will be considered and the neglected period between babyhood and school age will be one of the demonstration's chief concerns.

Through all the work that is planned it will be the effort of the committee to assist and not to dictate. The primary responsibility rests with the community and depends in its interest and cooperation.

The committee which will supervise the demonstrations has decided on the following conditions for the selection of the second community.

(1) The area from which the selection will be made includes those states south of the Mason Dixon Line and east of the Mississippi River.

(2) The following types of communities will be eligible: (a) a rural community of not more than approximately 30,000 population, and containing no town of more than 5,000 population; (b) an urban community of not more than approximately 20,000 population.

Nebraska Vegetable and Fruit Budget

Health from the garden, argued in the Public Health Nurse by Louise M. Murphy, describes the program effectually advocated by the Extension Department of the Nebraska State Agricultural College, and gives the reasons why vegetables and fruits must be on the table twice daily, and why certain green vegetables and oranges or tomatoes twice weekly. A "Food Habits Score Card" is issued by the department, and mothers, boys and girls, and college men and women have all alike been surprised at their low score because of the few vegetables eaten habitually.

On the basis of scores made and compared a family vegetable and fruit budget has been worked out on the basis that one-half of our vege-

tables and fruit are obtained from canned, and one-half from fresh, stored, or dried supplies. According to this budget each person should have two servings each of vegetables and fruits daily. Thus there should be: Seven servings of canned vegetables per week; seven servings of fresh, stored, and dried vegetables; seven servings of canned fruits per week; and seven of fresh, stored, or dried fruits.

The budget contemplates one-third cup of vegetables or fruits per serving, and 1.6 servings per pound of dried materials. The service is useful to indicate the number of varieties of vegetables and fruits that should be supplied by the garden of the average family. The score card furnishes blanks for record of the amount of home canning done, and proposes an inventory of the store room shelves in June as a check upon how satisfactory the budget has been.

Thus the dietary becomes the nucleus of all the year round activities, and intelligent planning is en-

couraged to replace the haphazard methods that usually obtain. The work is done with the fullest cooperation with the school nurses in setting up standards which constitute a safe balance in the daily diet.

Compulsory Accident Insurance in Agriculture

In a review of the compulsory accident insurance of agricultural workers in Italy, as provided for by law No. 1450 of August 23, 1917, it is stated that for an eight months period in 1919, for which the most accurate statistics are available, 23.5 per cent of the compensable accidents were due to the handling of tools, of which cutting tools were responsible for 17.9 per cent. Next in frequency came accidents caused by falls, 22.4 per cent. Fifteen per cent could specifically be charged to falls from trees. Transport apparatus was responsible for 15.7 per cent, and animals not attached to vehicles 11.5 per cent. (*Monthly Labor Rev.*, Jan. 1923).

Mental Hygiene in Maryland

SOME of the outstanding accomplishments of the former State Lunacy Commission of Maryland were the bond issues of over two million dollars which made possible the establishment of two new hospitals and the erection of new buildings at the existing institutions which, when the present plans are completed will provide for the entire system of state care; the removal of the insane and feeble-minded from county almshouses and jails and closing all but one of the county asylums; the establishment of a cooperative purchasing committee; the development of after care, reimbursing, and parole departments; a study of mental defectives by both the National Committee for the Feeble-minded and the National Committee for Mental Hygiene; and the completion of a building for the criminal insane.

Under the new state reorganization plan, the State Lunacy Commission with the addition of two members became the Board of Mental Hygiene.

The first report of the Commissioner, Dr. A. P. Herring, outlines the proposed work of the Board. It states that in the past energies have been largely devoted to the housing and custodial care of the insane and feeble-minded, but that there will be within the coming year sufficient accommodations for practically all of

the indigent insane. The report then calls attention to the matter of prevention and the study of medical service in the state institutions.

The proposed plan includes the establishment at the State University of a Department of Mental Hygiene, which would be conducted in the form of a mental hygiene clinic where the physicians from the state institutions would be in attendance, enabling them to come in contact with patients suffering from mental disorders in their incipient stages. An educational campaign is proposed for the purpose of creating public sentiment that will support the Board in its work for better care of the state wards. This campaign would include public talks before County Medical Associations, Women's Clubs, etc. The American Legion would cooperate.

It is also suggested that the Board visit each of the State institutions as soon as convenient and have a meeting of the entire staff of each hospital to talk over the local problems, especially as they relate to medical service, after care and occupational therapy.

The members of the Board are Hugh H. Young, M.D., Chairman, George H. Hocking, M.D., Henry J. Berkley, M.D., J. Albert Chatard, M.D., H. Findlay French, and Margaret S. Brogden.

The Sanitation of Bath Houses

OF ALL types of baths, cleansing, recreational, refreshing, and healing, the cleansing bath is the foremost in importance not only for the health of the individual but for the attainment of a higher degree of sanitation in a community. Describing the cleansing bath, William Paul Gerhard, C.E., says in his booklet, "The sanitation of Bath Houses" published by the William T. Comstock Company, New York:

It is generally conceded that the tepid douche or shower is the most sanitary type of cleansing bath. Second in importance are the baths taken in natural or in artificial pools for physical exercise, for the sake of recreation, for the love of the healthful sport of swimming. Such baths are in no sense intended as cleansing baths. It should be borne in mind that though swimming is one of the best forms of bodily exercise, if the water is badly polluted or the swimming hall overcrowded and badly ventilated it is not conducive to health. The hardening of the body can be accomplished after a warm tub bath by taking a tepid or cold douche administered from either a hand spray or overhead douche.

Healing baths being in the nature of a medical subject are not discussed by the author. Dr. Gerhard continues:

So far as the health of a city or a community is concerned, by far the most important are the people's cheap or free bathhouses. These should be located in the center of populous districts occupied by the working classes and by the poorer people in general. In large cities, obviously, more than one such bathhouse will be required. The ruling principle should be to decentralize the baths. In other words, rather than have one large bathhouse with hundreds of bath units, the large city should establish a number of smaller bathhouses, each accommodating a limited number of bathers. The buildings should have unpretentious exteriors; the interiors should be simple yet sanitary. Monumental buildings, from an architectural standpoint, are decidedly out of place. This criticism may, with some justification, be applied to some of the city

bathhouses erected in the past years.

It is customary to provide in people's bathhouses a few tub baths for women and for the smaller children, but the main equipment should consist of shower baths. This type of bath, the "rain bath," at it is sometimes called, is without shadow of a doubt the cleanest and most sanitary, because the water used in the ablution of the body flows away at once, without the body of the bather staying, as it necessarily does in the tub bath, in contact with the dirty, and sometimes contaminated water.

People's bathhouses should be municipal institutions and they should be kept open during all seasons of the year. It is at least debatable, in my judgment, whether or not to provide this type of bathhouse with a swimming pool in addition to the showers because of the additional cost involved in the construction of a watertight and sanitary pool, and further because of the formidable difficulty of keeping the pool water at all times pure and unobjectionable.

In the interest of municipal economy I have time and again made the feasible suggestion to utilize such rainbaths as are already provided in public schools during the evening

hours for the public at large. This has successfully been done in some of the schoolhouses of European countries. In smaller communities, such rain baths may be located in already existing buildings, for instance in the unused parts of the basement of a town hall, or in connection with a fire engine station, or even in connection with a village library building. The provision of cleansing baths in prosperous villages is a subject worthy of the special and closest attention of village trustees, of civic and health organizations, and of women's clubs.

The bathhouses of the second type have the much coveted additional provision for swimming in the pool. They are either open air baths, available only during the summer, as for example the river baths, the seaside baths, and the so-called wading and bathing pools provided in many city parks, or else they are enclosed bathhouses, heated during the winter season and thus made serviceable during the entire year. Their equipment consists of baths for cleansing, showers, and perhaps a few tub baths, and the swimming pool.

Municipal cleansing and pool baths should, if possible, be free to the public. Where the cost of maintenance is high a small fee might be charged for the use of the pool only, leaving the use of the shower baths free.

The public bathhouse with swimming pool may be a menace rather than boon to the community unless certain sanitary features are observed, states Dr. Gerhard.

As regards location, construction, and equipment, the room should be lofty, well-lighted, and adequately ventilated. The usual standard dimensions of a pool are 25 feet in width and 60 feet in length. A pool of this size has a water capacity of approximately from 78,200 to 106,400 U. S. gallons and is wide enough for five swimming lanes.

The pool should form a perfectly watertight basin. It may be built as a shell of steel, lined with concrete and with waterproofing, or else it may be constructed of stone work, brick work, or reinforced concrete masonry. Proper waterproofing of the bottom and sides is essential. The floor and the side walls of the pool should be finished with non-absorbent, impervious, durable and easily washable materials, preferably of a light color, and usually white. The choice of material lies between marble slabs, glazed or enameled brick, or ceramic glazed tiling. All corners must be well rounded to facilitate cleaning operations.

After a visit of inspection to many European swimming pools the writer suggested lining the sides of pools up to the water line, with light blue glazed tiles, with a darker horizontal border at the water level, and with white tiling above it. Many of the public pools abroad unquestionably owe their attractive appearance to this constructive and decorative feature, not less than to their usually crystal-clear water.

Dressing rooms should be located so that the bathers must pass through the cleansing rain bath before entering the pool.

*For the use of this material and the pictures illustrating the article we are indebted to the W. T. Comstock Company, New York City.

A device which is absolutely necessary to the cleaning of the pool is the scum gutter at the normal water level which serves to remove the lighter floating impurities due to perspiration and other debris. The floor should never slope or drain to the pool but should have floor outlets connected directly with the bathhouse sewer.

Dressing rooms located so that the bather must first pass through cleansing baths before entering the pool are another sanitary safeguard. The partitions of the dressing room should be made of structural opaque glass, of marble, or thin glazed tile blocks.

The most important feature of a swimming bath, from a sanitary viewpoint is not the pool itself but the preliminary cleansing bath. Dr. Gerhard further states. Sufficient attention is not always given to this essential part of a public bath house.

An adequate number of cleansing baths consisting of shower baths with hot and cold water connections, and footbaths should be provided.

To insure greater privacy, particularly for women, during the ablu-tion, which should be performed in the nude, before any bathing suits or trunks are put on, some compartments with light curtains should be fitted up. Partitions should be seven feet high, and may consist of marble or of other opaque and less costly material. The showers should have both upward and downward douche, the latter to perform a cleaning of the perineal region of the body. Free soap, preferably a disinfecting soap, and scrubbing brushes should be furnished by the bath attendant.

The footbaths are as necessary as the showers, yet I have not seen them provided for in any American bathhouse visited and inspected by me, whereas in European bathhouses they are quite the rule. The footbaths consist of either a long single trough, standing free on all sides and having tempered water flowing through it continuously, or they consist of a series of individual porcelain or glazed earthenware fixtures, arranged back-to-back in the center of the cleaning room, which is a more sanitary arrangement.

Much can be done to keep the water in a swimming pool sanitary by an efficient supervision and management of the bathers. A physical examination of the bathers while nude, to exclude

Foot baths, part of the equipment of every European bath, are often lacking in the similar American establishments.

the diseased, accomplishes much good, but it is difficult to enforce except in Y. M. C. A. buildings and in school or military baths.

Rules should be posted in conspicuous places and strictly enforced, requiring all bathers who wish to use the pool, to use the preliminary cleansing baths, and to pay attention in particular to the cleaning of the feet, for which special fixtures are provided and also of the loin regions. The use of soap should be made obligatory. Attention should also be drawn to the toilets provided and the bathers advised to use the urinals before entering the pool. The rules of conduct, posted in all dressing rooms, should state that all expectoration must take place either into cuspidors provided for, or into the scum gutter, but no spitting or blowing of the nose should be permitted in the pool. Offenders of the rules should be excluded from the privilege of using the swimming pool.

Bathers should either enter the pool nude, or wear the sterilized suits provided by the bath establishment. Male bathers may be permitted to wear small triangular loin cloths. Bathing

suits for women must be sterilized after each use, and undyed garments are recommended, as the dye contributes to the discoloration of the pool water. Smoking or chewing tobacco in the bathhouse should be absolutely forbidden.

Brief mention should be made of some details of the equipment of swimming pools, which consist in mechanical or structural accessories but which have no special sanitary significance. Every pool should have one or more descending stairs, usually placed at the shallow end, while ascending ladders may be located at the deep end. Both the stairs and the ladders must be so arranged that they will have no obstructing projections in the water. The built-in ladders are often constructed in concrete and lined with tiling. While the scum gutter usually performs the function of a life rail, in some cases a life rail of non-corrosive material is placed above the water surface.

Plumbing fixtures in a bathhouse should be of the most durable and sanitary type. Lavatories should be of heavy vitreous ware provided with "pop-up" waste fittings. Drinking bubble fountains should be of the type having a parabolic or slanting stream preventing the lips from touching the bubble orifice.

The ideal but practically unattainable standard for maintaining a pure water supply for the pool is to empty, clean, scour, and refill the pool once every twenty-four hours. The next best condition is to admit continuously a sufficient hourly flow of pure water (1/10 to 1/20 of the capacity of the pool) so that the water contents are changed at least once in 24 hours, and in addition, to empty and thoroughly clean the pool at least once a week. Cleanliness and cleanly habits of the bathers can eliminate much of the danger and are more important, Dr. Gerhard states, than methods of purifying contaminated water.

Methods of purifying water are by filtration, treatment with hypochlorite of calcium or with liquid chlorin,

ozone treatment, or sterilization by ultra-violet rays. Such treatment usually involves refiltration of water and only a small volume of the water is removed at a time. Moreover filtration does not remove the salts in solution, the ammonia, urine, or other polluting matter dissolved in the water, and in this lies the danger from artificial purifiers.

Interior view of Lurline Baths, San Francisco. Water should be kept level with the scum gutter so that all surface impurities are removed.

Bakers Decide for Physical Examination of Workers

Master bakers representing an out-put of more than three million loaves of bread weekly, decided April 17 at a New York conference of representatives of 150 cities, that all employees of plants under their control will have to undergo a physical examination at least twice a year, and agree to abstain from the use of tobacco during working hours. The resolution affects plants throughout the country.

A Small Town Health Exposition

"Let Health Rule in Bethel" was the slogan adopted by a little town of less than 2,000 population in Ohio, which claims to be the first town to adapt the health exposition idea to a small community.

Perhaps it was because Bethel is located near Cincinnati where the success of the health exposition held in 1921 had not yet faded out of mind that Bethel conceived the idea. The Bethel exposition was held March 18-24. The local *Journal* carried a prominent headline on all of its issues and numerous articles in the most prominent positions on the front page of the paper every issue, showed that the idea sold itself to the community.

Exhibits and a program of entertainment, motion pictures and addresses were held every afternoon and evening during "Health Week." The program started off with a health sermon at each church in the community on the first Sunday of the Exposition. Each grade in the public schools prepared a health playlet or some kind of appropriate health demonstration. This demonstration was the first thing on each program each afternoon and evening. It was followed by an address on the appropriate health subject given by some public health worker or physician from the nearby cities or the State Health Department, and that in turn by a health film related to the speaker's subject.

All citizens were asked to adorn their homes so that the town would present a festive appearance during "Health Week." Merchants were asked to decorate their stores and present special displays of their wares that help promote or maintain the health of the community.

The Exposition was prompted by a group of prominent citizens with the cooperation of most of the leading health organizations in Cincinnati, of their own County Health Commissioner and of the State Department of

Health. Among the special features of the "Health Week" was a demonstration by officials of the State Department of Health in Shick testing to determine immunity from diphtheria.

Cattaraugus County Demonstration

The first issue of the *Quarterly Bulletin* of the New York Health and Tuberculosis Demonstrations reports the steps taken by the Technical Board of the Milbank Foundation since the first of this year, in the development of the Cattaraugus County demonstration. A County Health District has been created with Dr. Leverett D. Bristol as its permanent health officer.

Olean has been chosen as the site of the County Laboratory, the nursing personnel has been increased, and a tuberculosis case finding survey started in the Clinton district of the county. Three scholarships for Cattaraugus County physicians have been offered by the Trudeau School, and a special Committee on Bovine Tuberculosis, consisting of Dr. Theobald Smith, Chairman, Dr. Veranus A. Moore, and Dr. William H. Park, has been appointed by the advisory council. This committee will work with the county authorities in the extension of bovine tuberculosis control measures; a \$6,000 appropriation having been made for the purpose.

Plans for the more adequate control of communicable disease, tuberculosis, and the development of Public Health Education are outlined.

Freezing and Thawing of Food

The preservation of food by freezing, with special reference to fish and meat, constitutes the basis of a study made by Walter A. Stiles and reported in *The Lancet*, its object being to determine the effects of changes which take place during prolonged periods of storage and to discover any detrimental effects from thawing.

Possible changes were studied from the standpoint of evaporation of water, loss of aromatic substances, chemical changes due to autolysis, changes due to the presence of water and oxygen made evident by the development of rancidity, and changes due to the activities of bacteria and molds.

Dehydration was reduced by close packing and by the prevention of air movement, by humidity control, by lowered temperature, and by the use of protective covering. Autolytic

changes are practically negligible during storage. Bacteria, however, survive at very low temperatures and Dr. Stiles points out that it is desirable to gut the large fish before storing them. Whether the vitamin content of food suffers in storage the study does not determine, but it is mentioned that the accessory food factor in butter was not diminished by preservation in cold storage.

The influence on foodstuffs of thawing is not cleared up. The more rapid the freezing, the more likely are the particles of the substances in the solid condition to retain their spatial relationships, and in such cases thawing slowly or rapidly conducted is likely to result in the re-formation of the original system. In slow freezing big crystals of ice may form which produce a separation which remains permanent upon thawing.

Slow thawing, though it gives more time for colloidal re-formation, possesses the objection that it affords more opportunity for the micro-organisms to attack the surface layers of the meat and hence reduced the time the meat can be kept after the thawing is finished.

Concerning the advantages of freezing and chilling as a means of preserving in cold storage, Dr. Stiles holds the advantage of the former to be so great that it should be the object of cold storage research to transfer as many foods as possible from the category of substances to which mere chilling can be applied to the category of foods where preservation is possible in the solid frozen state.

Harvey Dee Brown, who has for the past eight years been connected with the New York State Committee on Tuberculosis assumed March 19 the duties of Director of the Philadelphia Health Council and Tuberculosis Committee. It is to be expected that Mr. Brown's wide experience along tuberculosis, health, and social lines will forward the wide expansion of effort contemplated by the Philadelphia Council.

A bill now before the Connecticut Legislature calls for an expenditure of \$250,000 for the establishment of a psychiatric hospital and an annual appropriation for maintenance. The hospital would be located in New Haven, and Yale University offers to provide the site, funds for the support of a medical staff and for research in the field of mental disease. The hospital would act in conjunction with the Yale school of medicine.

American Association of Hospital Social Workers

A review and forecast of hospital social service is featured in the program of the annual meeting of the American Association for Social Workers, to take place in Washington, May 16 to 23, in connection with the National Conference of Social Work. The changes in hospitals, in administration, and in objectives involved in a service that maintains through the course of institutional and out-patient treatment the ideal of picturing the patient in all his relationships, and returning him to that environment restored as a useful, active unit, are well brought out in the topics arranged for discussion.

Such prominent workers as Misses M. Antoinette Cannon, president of the Association, Janet T. Thornton, N. F. Cummings, and Mabel Wilson are scheduled to recount the very specific studies being made by different sections of the society, while Frankwood E. Williams will outline the requirements of psychiatric social work, and Dr. William Healey, director of the Judge Baker Foundation, will review recent developments in psychiatric social work with children.

One Man Control of State Institutions

In November, 1920, the state Charities Aid Association of New York had ready for publication "A Valuation of a System for the Administration of State Institutions Through One-Man Control as Operated in Illinois." This report was the result of a survey of Illinois institutions made by Henry C. Wright. The institutions of the state had then been under the direction of the Department of Public Welfare (headed by a director) but a short time. It was not surprising that under the administration of the governor who sponsored this type of state control, fairly good results should have been secured rapidly. At that time this system seemed to compare favorably with the more conservative types of control that are common to the eastern states.

This report was completed two months before a new governor was to be inaugurated. Eighteen months after the inauguration (July, 1922) an addendum was written and the entire study published by the Association in November, 1922. On January 1, 1921, New York and Massachusetts had also inaugurated governors. In Massachusetts and Illinois a republican succeeded a republican while in New

York a republican succeeded a democrat. It might naturally have been assumed that there would be many changes in personnel in New York, but during the eighteen months specified no changes took place in the heads of civil state hospitals. In Massachusetts, one retired by age, one died, and both positions were filled from promotion lists. In Illinois four heads of state hospitals were replaced by doctors from general practice, and four heads of other institutions by laymen without recognized qualifications.

The New England Industrial Nurses Association

The speaker for the April meeting of the New England Industrial Nurses Association was Mr. John Garvey, personnel manager of the Dennison Manufacturing Company, Framingham, Mass., on the topic "Is the Industrial Nurse an Asset or a Liability to Industry?"
